# Monitoring and Research Plan to Support the Glen Canyon Dam Adaptive Management Program, Fiscal Years 2007–11

Prepared by the USGS Grand Canyon Monitoring and Research Center

## Chapter 1. Introduction, Purpose, and Organization

### Introduction

The Glen Canyon Dam Adaptive Management Program (GCDAMP) was established in early 1997 by the Secretary of the Interior to implement the Grand Canyon Protection Act of 1992 (GCPA), the 1995 Operation of Glen Canyon Dam Final Environmental Impact Statement (EIS), and the 1996 Record of Decision (ROD). Adaptive management in Grand Canyon was envisioned as a new paradigm to address environmental problems related to the operation of Glen Canyon Dam (GCD) through the dynamic interplay of ecosystem science, collaboration, and management. The GCDAMP consists of five components: the Adaptive Management Work Group (AMWG), the Secretary of the Interior's Designee, the Technical Work Group (TWG), the U.S. Geological Survey's (USGS) Grand Canyon Monitoring and Research Center (GCMRC), and Independent Review Panels (IRPs). Each entity has a specific role:

1. The **Adaptive Management Work Group** is a Federal Advisory Committee composed of 25 members, who include representatives from Federal and State resource management agencies, the seven Colorado River Basin States, Native American tribes, environmental groups, recreation interests, and contractors of Federal power from Glen Canyon Dam. The AMWG reviews and develops alternative dam operations and conservation measures and provides recommendations to the Secretary of the Interior in order to fulfill the Department of the Interior's (DOI) obligations under the GCPA.
2. The **Secretary of the Interior's Designee** serves as the chair of the AMWG and provides a direct link between the AMWG and the Secretary of the Interior.
3. The **Technical Work Group** translates AMWG policy and goals into information needs, provides questions that serve as the basis for long-term monitoring and research activities, conveys research results to AMWG members, and makes recommendations on budgets and work plans.
4. The **Grand Canyon Monitoring and Research Center** provides credible, objective scientific information on the effects of GCD operation and related natural, cultural, and recreational resources along the Colorado River from GCD to Lake Mead.

5. The **Independent Review Panels** assess program proposals and accomplishments to ensure scientific objectivity and credibility. A group of Science Advisors (SA), academic experts in fields germane to studies within the scope of the GCDAMP, serves as an IRP.

## Science Planning Process

The GCDAMP uses a planning process to develop a credible, objective science program that is responsive to the goals and priority needs identified by the AMWG. Since 1996, the AMWG has used a structured process for specifying their information needs. Through a series of workshops, a hierarchy of goals, objectives, core-monitoring information needs (CMINs), and research information needs (RINs) was developed. The AMWG also specified 12 GCDAMP goals to guide planning, monitoring, and research. However, the list of objectives grew to more than 40 and information needs to more than 160, complicating science planning and priority setting.

Given this complexity, the AMWG identified the need for a different approach in 2004 and identified 5 priority questions and 12 GCDAMP goals to focus science activities. In 2005, to further focus science planning, the GCMRC initiated two knowledge assessment workshops that identified areas of scientific uncertainty and strategic science questions (SSQs) related to the five priority questions.

The 12 GCDAMP goals are used to organize the science activities articulated in this document, the Monitoring and Research Plan to Support Glen Canyon Dam Adaptive Management Program, Fiscal Years 2007–11 (hereafter MRP). Monitoring and research activities are focused on AMWG priority questions and SSQs that grew out of the knowledge assessment workshops (appendix A). In some cases, CMINs and RINs are referenced to clarify the intent of AMWG priority questions and SSQs.

The MRP was developed by the GCMRC in cooperation with the GCDAMP Science Planning Group (SPG) to specify monitoring and research programs consistent with both the management-side Final Draft GCDAMP Strategic Plan (AMPSP) and the science-side GCMRC Strategic Science Plan (SSP). The AMPSP was drafted by GCDAMP and the GCMRC in August 2001 and refined in 2003. The plan identifies the AMWG's vision and mission, principles, goals, management objectives, information needs, and management actions. The SSP was developed by the GCMRC and GCDAMP and identifies strategies for providing science information that are consistent with the AMPSP and responsive to the goals, management objectives, and priority questions of GCDAMP participants.

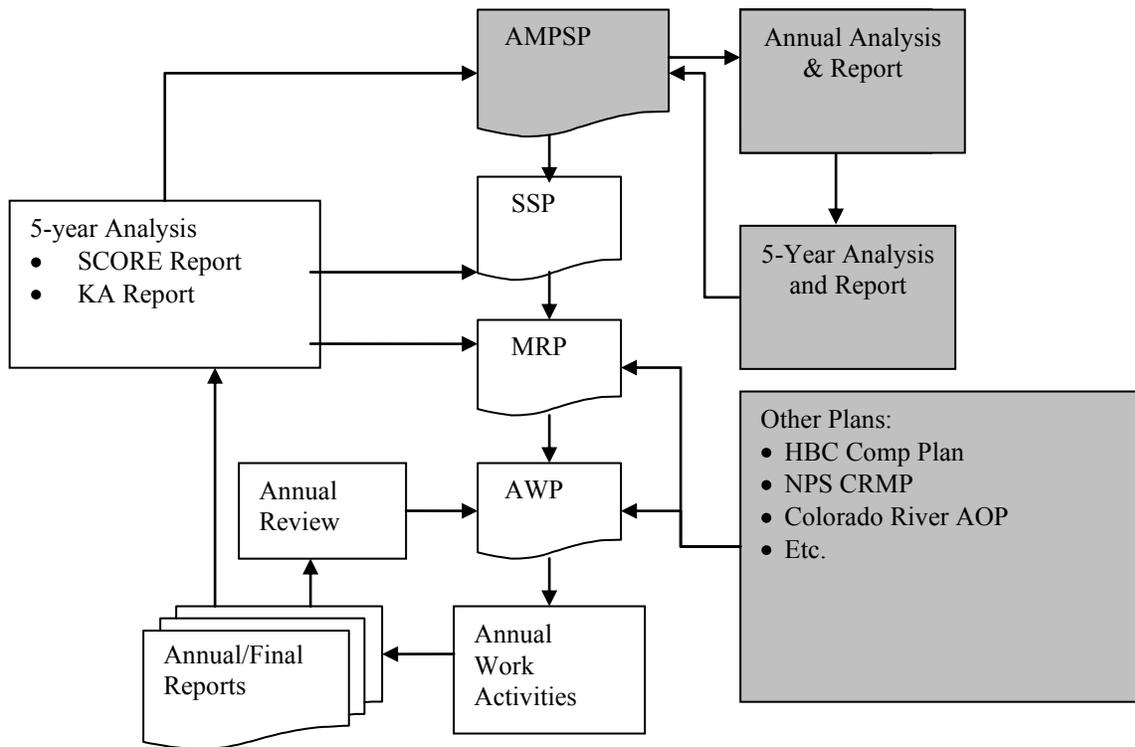

Implementation of the MRP will be described in the GCMRC biennial work plan, which will identify the scope, objectives, and budget for monitoring and research projects during a 2-year period. In the meantime, a transitional annual work plan was developed for fiscal years (FY) 2007 (FY2007) and 2008 (FY2008), while the Long-Term Experimental Plan (LTEP) is being prepared. The LTEP is a funding plan for a temperature control device (TCD), and a recovery program for humpback chub (*Gila cypha*) (HBC) in Grand Canyon. The projects identified in the transitional FY2007 GCDAMP are summarized in the MRP.

The FY2007 annual work plan will be the foundation for the development of the FY2009–10 biennial work plan. This foundation will be augmented by new information that is anticipated in FY2007 and FY2008, which includes (1) the completion of an LTEP, (2)

implementation of a process for evaluating core-monitoring projects, and (3) development of a approach for conducting ecosystem science.

Figure 1 depicts the flow of information in the science planning and implementation process. Annually, the GCMRC will report on accomplishments related to projects from the biennial work plan and evaluate how science has advanced knowledge relative to GCDAMP goals and management objectives. At 5-year intervals, the GCMRC will synthesize new scientific information in an updated State of the Colorado River Ecosystem in Grand Canyon (SCORE) report (Gloss and others, 2005), Knowledge Assessment Report (KAR) (Melis and others, 2006), and other reports, as appropriate. Priority information needs and science questions will be evaluated by scientists and managers to determine what program revisions are needed. This includes the development of revised SSP and MRP documents.

The MRP also incorporates information from GCDAMP and other resource management agency plans such as the National Park Service (NPS) Colorado River Management Plan (CRMP) and the 1993 Humpback Chub Comprehensive Plan, as amended. The GCMRC will provide science information that is consistent with and supports these plans, as appropriate.

**Figure 1.** Collaborative science planning and implementation process. The Glen Canyon Dam Adaptive Management Program and the Department of the Interior have lead responsibility for the shaded boxes. The Grand Canyon Monitoring and Research Center has lead responsibility for the boxes that are not shaded.

GCMRC science planning is done in conjunction with planning by the GCDAMP to specify or update priority goals/questions, information needs, and management actions. Concurrent planning will help ensure the science program is aligned with current management priorities. GCDAMP and the DOI need to define priorities for GCDAMP resources such as HBC, sandbars, and camping beach. This information will allow the GCMRC to design targeted monitoring and research projects that are responsive to management goals.

## Purpose

This MRP will describe the scope of a 5-year monitoring and research program to address priority goals, questions, and information needs specified by the GCDAMP. The plan will identify specific science needs for FY2007; more general needs will be defined for FY2008–11.

The MRP is designed to be consistent with the GCMRC SSP, which emphasizes four key components:

- Incorporating interdisciplinary, integrated river science
- Building bridges between science and management
- Addressing priority AMWG goals/questions and associated SSQs as articulated in the KAR (appendix A)
- Addressing critical monitoring and research needs outside the scope of the GCDAMP

## Organization

Chapter 2 of the MRP describes the monitoring and research activities for FY2007–11 related to the 12 goals in the GCDAMP Strategic Plan. Monitoring and research activities are generally organized into one of three categories:

1. **Core-monitoring activities** are scientifically validated protocols to assess the condition and trend of priority GCDAMP resources (e.g., HBC, sediment, the food base, etc.).
2. **Research and development activities** are projects aimed at (1) addressing hypotheses or information needs related to a priority GCDAMP resource or (2) developing/testing new technologies or monitoring procedures.
3. **Long-term experimental activities** are a suite of flow and nonflow treatments and management actions designed to improve the condition of target resources (e.g., HBC, cultural sites, sediment, etc.) and, through monitoring and research, allow for an understanding of the relationship between treatment/management actions and target resources.

The five priority questions identified by the AMWG and the related SSQs (appendix A) were used to organize monitoring and research activities. The MRP is focused on these priority and science questions. Other GCDAMP goals and information needs will still be pursued, but with less intensity until priority issues of concern are resolved and monies can be reprogrammed or obtained through alternative sources.

All monitoring and research activities described in chapter 2 will be designed and carried out in an interdisciplinary fashion as discussed later in the introduction.

## Core-Monitoring Activities

Core Monitoring: Consistent, long-term, repeated measurements using scientifically accepted protocols to measure status and trends of key resources to answer specific questions. Core monitoring is implemented on a fixed schedule regardless of budget or other circumstances (e.g., water year, experimental flows, temperature control, stocking strategy, nonnative control, etc.) affecting target resources (Bureau of Reclamation, 2001).

The development of a long-term core-monitoring plan for the GCDAMP has been essential since the inception of the program in 1996. However, it has remained an elusive goal for a variety of reasons. First, the systematic development of monitoring programs generally involves a protocol evaluation panel (PEP) for each key resource area; several years of pilot testing of monitoring protocols; a period of analysis, synthesis, and reevaluation; and the implementation of long-term monitoring protocols. This process was initiated in 1998 and is in progress for many elements of the program today (e.g., terrestrial ecosystems, archaeological and tribal resources, the aquatic food base, recreation, and fisheries). Other factors have hindered rapid development of a core-monitoring plan, including

- Lack of agreement among GCDAMP stakeholders about scope, purpose, and objectives of core-monitoring projects under the GCDAMP
- Lack of agreement among GCDAMP stakeholders and scientists about what defines core monitoring as opposed to other kinds of monitoring, such as monitoring the effectiveness of experimental or management actions
- Lack of agreement about the required levels of precision and accuracy in monitoring data necessary to achieve program goals

A Provisional Core Monitoring Plan (PCMP) (Fairley and others, 2005) was drafted by the GCMRC in cooperation with a GCDAMP core-monitoring team. However, the plan only addressed a few highly developed monitoring efforts (so-called “green” projects) and was not adopted by the TWG or the AMWG and therefore not finalized. Nevertheless, the PCMP represents the best guidance currently available for the development of core-monitoring projects for FY2007–11.

Current monitoring projects associated with GCDAMP resources will be evaluated by the GCMRC and the TWG. Evaluation of the suitability of projects for core monitoring is critical because these activities have significant budget implications for the science program that could limit the flexibility of the GCMRC and the GCDAMP to respond to high-priority research needs. Accordingly, all projects will undergo the following technical evaluation process for determining core-monitoring status:

1. **General core-monitoring proposal:** In FY2007, the GCMRC will draft a core-monitoring proposal that identifies by resource area the goals, objectives, scope, schedule, and funding for each proposed core-monitoring project. The proposal will be based on AMWG priorities, identified information needs, the feasibility of developing monitoring protocols to meet those needs, and other relevant information. The proposal will be provided to the TWG for review.
2. **Information needs workshop:** The GCMRC will conduct an annual TWG workshop to refine recommendations on management goals, information needs, and the scope of all

monitoring projects that will be evaluated for core-monitoring status in a given fiscal year. The workshop will also identify questions that managers would like to have addressed in the follow-up PEP for each resource goal.

3. **Protocol Evaluation Panel review:** For each resource goal, the GCMRC will convene a PEP to evaluate the results of the information needs workshop, review the results of past monitoring efforts and relevant research and development activities, and recommend monitoring protocols and other technical specifications for the monitoring project.
4. **Core-Monitoring Program reports:** Based on the results of the workshop and the PEP evaluation, the GCMRC will prepare a report to the TWG for each project being evaluated for core-monitoring status. These reports will provide the TWG with sufficient information to evaluate individual projects. The reports will include the following information:
  - AMWG goal(s) addressed
  - Project title
  - Principal investigator(s)
  - Geographic scope
  - Justification for monitoring effort
  - Project goals, tasks, and schedule by task
  - Key science questions and managers' information needs addressed
  - Linkage to other resources processes and models
  - Monitoring protocols, including sampling designs, level of data resolution, accuracy and precision assessment, etc.
  - Expected outcomes, including outputs by fiscal year, reports, guidelines, models, etc.
  - Costs of project by fiscal year

Projects approved by the TWG for core-monitoring status will receive first consideration for funding each year and will not undergo the same annual competitive review as other projects. However, the projects will be reviewed during the development of the biennial work plan to incorporate new findings and monitoring techniques to improve their effectiveness. A more comprehensive review will be conducted at 5-year intervals.

The focus of the evaluation process described above will be to evaluate for core-monitoring status “green” projects that have undergone a PEP evaluation, have been piloted and the results peer reviewed, and have been implemented for one or more years using methods that are deemed to be adequate for long-term monitoring. Projects in this category and their anticipated review schedule include

- Downstream surface-water parameters (discharge, stage measurements) and water-quality parameters related to sediment (e.g., suspended-sediment transport measurements and modeling) (FY2007)
- Status of Lees Ferry rainbow trout (RBT) (FY2007)

- Status of HBC in the Little Colorado River (LCR) (to be reviewed by a PEP using data on the Colorado River population) (FY2008)

In addition, several monitoring projects that have undergone a PEP review have subsequently undergone a period of research and development or pilot testing and are now ready for a second PEP review before being implemented as part of the long-term core-monitoring plan. Other projects, such as food base and cultural resource studies, have only recently started their multiyear research and development phase. These projects will be brought forward for review over the course of the next 5 years with the goal of having a fully developed core-monitoring program in place by FY2011. The proposed schedule of projects for review is as follows:

- Sand storage monitoring (FY2007)
- Terrestrial ecosystem monitoring (TEM) (FY2007)
- Status of HBC in the mainstem of the Colorado River (to be reviewed through PEP with LCR population) (FY2008)
- Integrated quality-of-water (IQW) monitoring (Lake Powell and downstream parameters, including specific conductivity, dissolved oxygen, and temperature) (FY2009)
- Kanab ambersnail (KAS) habitat and population monitoring (FY2009)
- Camping beach monitoring (FY2009)
- Cultural site monitoring (archaeological, traditional cultural properties [TCPs]) (FY2010)
- Aquatic food base monitoring (FY2010–11)

Monitoring of TCPs and tribal values in the Colorado River ecosystem (CRE) is a component of the GCDAMP; however, the GCMRC faces a number of challenges in integrating tribal perspectives into core monitoring. This is in part because of differing perceptions about what constitutes ecosystem “health,” and also because most of the tribes have been reluctant to formally identify their TCPs. In many cases, a tribe’s resource interests are tied to culturally important places in the river corridor, the locations of which are considered to be proprietary information. Without a clear articulation of the tribes’ needs for monitoring data, it is impossible for the GCMRC to develop monitoring projects to meet tribal needs.

The tribes were funded by the GCDAMP in FY2006 to define their monitoring projects, methods, and metrics for evaluating the resources and places of tribal interest in the CRE. These projects are scheduled to go to the TWG for review and discussion in FY2007. If the methods and rationales for these proposed monitoring projects are shared with the GCDAMP and subjected to peer review, they may fit within the GCDAMP science program as currently defined. Otherwise, the information derived from the tribal monitoring effort may be more appropriately incorporated into the GCDAMP decision making process via ongoing consultation among the tribes, GCDAMP stakeholders, and DOI agencies. The GCMRC will describe the tribal monitoring component of the 5-year science program with more specificity after tribal monitoring needs are defined and sent for TWG review in FY2007.

## **Research and Development Activities**

Research and development activities include projects aimed at (1) addressing hypotheses or information needs related to a priority GCDAMP resource(s) and (2) developing and testing new technologies or monitoring procedures. Examples of research and development goals included in the MRP are as follows:

1. Link whole-system carbon cycling to food webs in the Colorado River, which will provide the basis for the food base-monitoring program
2. Investigate remote passive integrated transponder (PIT) tag-reading technology
3. Investigate sonic tag technology
4. Develop advanced downstream flow, temperature, and suspended-sediment models
5. Evaluate quality of historical remote-sensing imagery for change detection
6. Evaluate statistically HBC habitat preferences

In the MRP, research and development projects will focus on addressing specific information needs and hypotheses related to the AMWG priority SSQs and the development and refinement of monitoring protocols.

## **Long-Term Experimental Activities**

The MRP will be consistent with and implement the LTEP, which will be developed by the Bureau of Reclamation (Reclamation) in compliance with the National Environmental Policy Act. It is assumed that the LTEP will reflect the “hybrid” experimental design embraced by the GCDAMP. The hybrid experimental design incorporates assessments of management actions, or activities that provide a demonstrated resource response and no longer require further research, and experimental treatments. Coldwater fish control developed in the 2003–06 research program is an example of a management action, having been proven effective at reducing the abundance and distribution of RBT within treatment reaches near the confluence of the LCR. Therefore, further GCMRC research on this activity is not included in the MRP. Future implementation of this action should be carried out primarily by the appropriate land and resource management agencies. However, the GCMRC will continue to evaluate the effects of trout removal on native fish populations.

The LTEP will include research to test various hypotheses associated with different experimental flows from GCD, such as evaluation of the effects of ramping rates on downstream resources, triggers for steady flows, or short-duration flow spikes on aquatic productivity or drift. One area of emphasis will be further research on the use of beach/habitat-building flows (BHBF), or controlled floods, to build sandbars that support several GCDAMP goals, such as providing fish and riparian habitat and camping beaches. BHBFs are triggered by predetermined target levels of natural deposits of sediment in the mainstem Colorado River below the Paria and Little Colorado Rivers. For budgeting purposes, in the FY2007–11 period, the GCMRC anticipates two additional BHBF tests. Estimated costs for the monitoring and research associated with the BHBF tests are \$1 to \$1.9 million per test.

In 2003, the GCDAMP established a fund to pay for experimental research projects so that they can be conducted without financially impacting other aspects of the science program. The current balance of the experimental fund at the end of the FY2007 is anticipated to be

approximately \$900,000. An additional \$500,000 will be set aside by the GCMRC annually in an account at Reclamation to fund the BHBF tests and other research related to experimental efforts.<sup>1</sup> Deposits to the experimental account will cease when the balance reaches \$2.5 million.

Consistent with the available funds, the GCMRC will develop an LTEP work plan with GCDAMP. Experimental research will be coordinated with ongoing monitoring and research projects to maximize cost effectiveness.

NOTE: The LTEP will be implemented following approval by the Secretary of the Interior and completion of environmental compliance requirements (e.g., National Environmental Policy Act, Endangered Species Act). The GCMRC will provide scientific information to support the environmental compliance process, as requested and feasible. Once the LTEP is finalized, the agreed-upon experimental actions will be incorporated into the MRP.

## **Integrated and Interdisciplinary Science**

The GCMRC will emphasize an integrated, interdisciplinary science approach during the next 5 years. An interdisciplinary approach is the only practical way to link the physical, biological, and sociocultural components of the CRE. To provide a framework for integrating scientific activities, the MRP is structured around overarching SSQs (appendix A). The science approach to be developed in FY2007 will emphasize four areas, which are discussed in greater detail below. This approach will increase the likelihood of providing definitive answers to SSQs in the next 5 years.

## **Staffing and Organizational Capacity**

In FY2006, GCMRC staff was realigned to create a Deputy Chief position that is responsible for supervising day-to-day operations and ensuring that integrated/interdisciplinary procedures are used in the science program. In addition, in FY2008, the GCMRC proposes to recruit a part-time/visiting ecosystem scientist/ecologist to work with GCMRC staff and cooperators to pursue integrated, interdisciplinary ecosystem-science strategies. Possible strategies include the application of the CRE conceptual model to science planning and project design, and the evaluation of decision-support tools to improve the application of science information in the GCDAMP process (see below). The efficacy of hiring the visiting scientist will be reviewed based on the SA-proposed FY2007 recommendations for incorporating an ecosystem science approach into the current science program (see below).

## **Conceptual Ecosystem Model Enhancement**

In 1998, Walters and others (2000) conducted a workshop to assist scientists and managers in developing a conceptual model of the CRE as affected by GCD operations. The model proved to be useful for understanding the relationship among ecosystem components, identifying knowledge gaps, and predicting the response of some ecosystem components to policy change. However, the model was unable to predict the effects of policy decisions on several key areas, such as long-term sediment storage, fisheries response to habitat restoration, and socioeconomic effects. Expanded design, development, and use of the conceptual ecosystem

---

<sup>1</sup> The Grand Canyon Monitoring and Research Center will set aside funds for experimental research projects under Project ADM 12.E1.07 (FY2007–08 Carry Forward Fund for Experiment Phase II), which is described in the FY2007 annual work plan.

model (CEM) are needed to increase its utility in ecosystem science planning and management processes and to provide information that is relevant to each high-priority AMWG goal/question.

In FY2007–08, the GCMRC will work with the SA to incorporate more robust integrated, interdisciplinary science approaches into its overall program effort. The SA review will develop practical methods to improve the ability of the GCMRC to address priority GCDAMP information needs. An objective of the SA review will be to evaluate the redesign and expansion of the conceptual CRE model. A preliminary list of priority expansions of the CRE model include

- Expanding the fishery elements to address coldwater and warmwater fish predation on HBC young-of-year (YoY), HBC habitat use, etc.
- Modeling outcomes of nonflow management activities (e.g., operation of a TCD, mechanical removal of nonnative fish, translocation efforts for HBC, tributary triggers for BHBFs)
- Linking Lake Powell and downstream temperature simulations to fine sediment, food web, and fisheries submodels
- Expanding the model to provide a broader landscape perspective by incorporating Lake Powell, the Little Colorado and Paria Rivers, and terrestrial habitats in the CRE
- Enhancing the use of climatic input data and simulations
- Researching recreational use and campsite size, abundance, and distribution
- Developing cultural site change and protection strategies (archaeological sites, TCPs)
- Simulating financial impacts coupled to the flow/dam operations submodels

## Sediment Dynamics

Sediment and sand supplies are critical ecosystem components important to the long-term maintenance of several priority GCDAMP resources. For example, high-elevation sandbars provide camping beaches, support riparian habitat and associated wildlife, and contribute aeolian sand that affords protection for some archaeological sites in close proximity to the river. Sandbars also provide backwater habitats that are warmer than main-channel habitats and may be important to the growth and survival of HBC and other native fishes. As part of the experimental program, two BHBF experiments are planned for the FY2007–11 period to enhance sand dynamics and related resources, provided sediment triggers are reached. A focus of these experiments and the BHBF work plan will be to determine the relationships between the creation and maintenance of sandbars and these GCDAMP resources.

## Temperature Control Device Evaluation and Planning

It is essential that adopting the use of a TCD as a management policy be accompanied by a commitment to a comprehensive long-term level of research and monitoring that provides timely results in evaluating its value as a management tool (GCDAMP SA, 2003).

The design and possible construction of a TCD for GCD has been identified as a priority activity for the GCDAMP in the FY2007–11 period. The objective of the TCD would be to allow for regulation of the temperatures and other water-quality parameters (e.g., dissolved oxygen) of

water released from GCD. The primary goal would be to create mainstem water-temperature conditions that promote natural reproduction and recruitment of HBC in the mainstem of the Colorado River. Other potential effects of a TCD may include

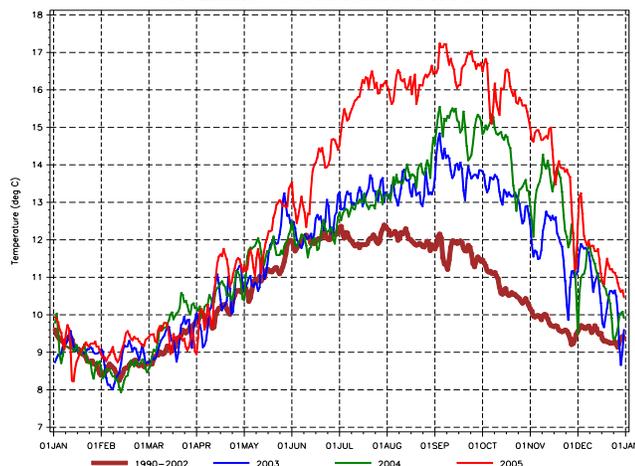

- Increased aquatic productivity
- Increased distribution and abundance of native fishes
- Increased trout productivity in the Lees Ferry reach and associated improvements in the trout fishery
- Increased satisfaction with the river recreation experience

The primary risk associated with a TCD involves the proliferation of warmwater nonnative fishes that may compete with or prey upon native fishes. (Warmwater nonnative fishes are considered a threat to the HBC and other native fishes in the CRE.)

Since 2003, the Colorado River water temperatures below GCD have been increasing (fig. 2) because of prolonged drought conditions and lower water levels in Lake Powell. The low water levels have resulted in warmer water passing through the dam than would have occurred under higher reservoir elevations. These warmer releases are correlated with a number of changes in the fisheries, including

1. Evidence of mainstem spawning of HBC, which is indicated by the presence of YoY HBC at river mile 30 on the Colorado River
2. Increased numbers of juvenile HBC in comparison to recent years
3. A decline in the RBT population in the Lees Ferry reach possibly owing to reductions in dissolved oxygen associated with the warmer GCD releases
4. Increased observations of warmwater nonnative fishes that may prey upon or compete with native fishes

Recent Mainstem Warming Patterns above mouth of Little Colorado River

**Figure 2.** Recent mainstem warming patterns above the mouth of the Little Colorado River. The natural warming of the river occurred at least through water year 2006 and provided a unique opportunity to study the effects of warmer water on Colorado River ecosystem resources before the possible construction of a temperature control device.

The GCMRC proposes the following studies and activities to evaluate the effects of natural river warming and to assist in decisions related to funding and design of a TCD:

1. Develop and test a water-temperature model to better predict the effects of GCD operations on downstream water temperature and associated shoreline habitats
2. Synthesize water-quality data for Lake Powell and link Lake Powell to the Colorado River quality-of-water models
3. Synthesize and evaluate currently available water-temperature data focused on the Colorado River near the confluence of the LCR
4. Develop and test a nonnative fish management plan that will (1) assess the implications and expected response of both the native and nonnative fisheries communities to warmer water and (2) identify methods of control that will be tested/refined (FY2007–11)
5. Continue to gather and evaluate baseline data on the effects of natural warming of river temperatures on the distribution, abundance, and reproductive success of native and nonnative fishes (FY2007–11)
6. Work with the U.S. Fish and Wildlife Service (USFWS) to develop an HBC genetics management plan and a related plan for one or more refuges for HBC to avert the catastrophic decline of HBC populations associated with the proliferation of nonnative fishes
7. Organize and conduct a workshop to develop a comprehensive science plan to address the operation of a TCD

### **Critical Monitoring and Research Needs Outside of the Colorado River Ecosystem**

The uses of GCDAMP funds are currently focused on addressing the impacts of dam operations on resources in the immediate Colorado River corridor downstream of GCD to Lake Mead. As a result, some potentially significant external threats to CRE resources that are relevant to the GCDAMP mission and goals are not being addressed. USGS will seek funding outside the GCDAMP to address three critical needs: (1) threats to the LCR, (2) Lake Powell water quality, and (3) effects of climate change and drought in the Colorado River Basin.

#### **Threats to the Little Colorado River**

The lower reach of the LCR located just above its confluence with the main Colorado River is critical spawning and rearing habitat for virtually the entire endangered HBC population in Grand Canyon. However, only the lower few miles of the LCR watershed are being addressed by the GCDAMP. Possible spills of hazardous materials and water-quality contamination in upstream areas of the LCR watershed have been identified by the USFWS as a significant threat to the endangered HBC. The USFWS has identified the need to develop a hazardous material spill response plan to help avert the catastrophic loss of the HBC population.

The GCMRC proposes the following activities to support this need:

- Enhance the existing stream gage in the lower LCR to include water-quality sampling consistent with the mainstem quality-of-water program, which would improve the capacity to detect changes in water quality resulting from contamination in the upper watershed
- Synthesize existing historical hydrology, sediment, water-quality, and land-use information in the LCR Basin in relation to habitat requirements of HBC in the lower reach of the LCR
- Assess the risk of water contamination from various sources in the LCR

## Lake Powell Water Quality

A primary determinant of water quality in the Colorado River below GCD is the water released from Lake Powell. In addition, the water-quality characteristics of Lake Powell have significant implications for the design of a TCD to regulate the releases from GCD. While extensive physical and biological data on Lake Powell water quality have been collected for more than two decades, the data have not been synthesized or subjected to analysis and modeling to simulate both temperature and dissolved oxygen characteristics for GCD releases. Under this activity, historical Lake Powell data will be synthesized to identify trends in water quality. In addition, trends in dam operations, basin hydrology, and climate variability will be linked with biological data both in the reservoir and downstream of GCD (i.e., aquatic productivity and both nonnative and native fish trends). Information from this activity will support efforts to model both Lake Powell quality of water and downstream release characteristics associated with use and testing of a TCD. These assessments could significantly advance knowledge of potential future water quality in Lake Powell and the appropriate design and operation of the TCD. This study will be carried out in partnership with Reclamation.

## Effects of Climate Change and Drought

Long-term drought and climate change have significant implications for decisions about future water management and hydropower production in the Colorado River Basin and the conservation of natural resources in Grand Canyon. Runoff in 2000–04 in the upper Colorado River Basin was the lowest in the period of record; Lake Powell is currently (2006) less than 50% full. Water managers increasingly need predictive capability for climate change and related drought forecasting over annual-to-decadal time spans. However, the causal mechanisms of drought are not presently well enough understood to make accurate predictions to meet the needs of managers at even seasonal-to-annual scales. In addition, continued climate change and long-term drought will have potentially significant implications for several identified strategies for the operation of GCD to attain a variety of GCDAMP goals (e.g., preservation of native fishes, sediment, cultural resources, and recreation).

Under this research initiative, basin-scale climate studies will be conducted on how new climate information could be used by water and other resource managers in the GCDAMP program. The focus will be on (1) how climate forecast information could be used in decisions related to the operation of GCD and other Colorado River Storage Project operations, and (2) the role of climate variability and hydrological variance (upper-basin runoff versus the flood frequency of major tributaries below the dam) in ecosystem responses and their relationship to operation of GCD. This study will be carried out in cooperation with the National Oceanic and Atmospheric Administration and Reclamation.

## **CHAPTER 2. Proposed FY2007–11 Monitoring and Research Plan Activities**

Proposed science activities for FY2007–11 are summarized in table 1. These activities are categorized as core monitoring, research and development, and long-term experiments. All proposed science activities are related to both GCDAMP goals and AMWG priorities.

Chapter 2 summarizes the core-monitoring, long-term experimental, and research and development activities for GCDAMP goals 1–11 and describes general activities for goal 12. The chapter also discusses efforts to integrate monitoring and research activities across goals.

SSQs and information needs specified in the SSP (2007) are being used to drive monitoring and research activities for the next 5 years. In addition, GCMRC developed a crosswalk table (appendix A) showing how the RINs in the GCDAMP Strategic Plan relate to the SSQs in the SSP. Through a review of this table, GCMRC identified five new SSQs to be added to the MRP. These include

- **SSQ RIN 1:** What habitats and habitat characteristics, if any, will enhance survival, growth, and reproduction of native Grand Canyon fishes, especially HBC, in the mainstem Colorado River?
- **SSQ RIN 2:** What are the most effective strategies and control methods to limit nonnative fish predation on, and competition with, native fishes?
- **SSQ RIN 3:** What life stage(s) of RBT pose the greatest threat to HBC and other native fishes in Grand Canyon? Are the RBT that threaten native fishes in Grand Canyon produced above or below the mouth of the Paria River?
- **SSQ RIN 4:** What are the effects of ramping rates on sediment transport and sandbar stability?
- **SSQ RIN 5:** What is the rate of change in eddy storage (erosion) during time intervals between BHBFs?

In some cases, proposed research and monitoring activities concentrate on a single strategic science question. For example, most of the goal 8 research and monitoring activities are directed at answering this question: Is there a “flow-only” operation (i.e., a strategy for dam releases, including managing tributary inputs with BHBFs, without sediment augmentation) that will restore and maintain sandbar habitats over decadal time scales?

For other goals, multiple SSQs and information needs have been identified because of the complexity of the issues and the current state of knowledge about how to best achieve a goal. For example, seven SSQs, two core-monitoring information needs, and two RINs are identified for goal 2 (native fish/HBC). It is impractical to “answer” all of the questions and information needs within the scope of this 5-year MRP. Answering the stated SSQs and information needs will require research and modeling on several fronts over an extended period of time. The philosophy used by the GCMRC in preparing the MRP was to simply address multiple SSQs, in the belief that proceeding on multiple fronts will provide for a more balanced, robust research program. It should be noted that long-term experimental activities that have yet to be defined will greatly contribute to addressing the identified SSQs and information needs. Once the long-term

experimental program is finalized by the GCDAMP and the DOI, GCMRC will implement the experimental science plan in cooperation with GCDAMP. The intent is that the science plan will be driven by specific hypotheses and science questions.

**Table 1.** Summary of core-monitoring, research and development, and experimental activities described in the Monitoring and Research Plan to Support Glen Canyon Dam Adaptive Management Program, Fiscal Years 2007–11. Several long-term experimental activities currently under discussion are not reflected in the table; additional experimental activities will be specified pending the finalization of the LTEP. Activities address Glen Canyon Dam Adaptive Management Program (GCDAMP) goals 1–12 in relation to science questions and information needs. Priority and related strategic science questions are paraphrased from the Draft GCMRC SSP (appendix A). Information needs are paraphrased from the GCDAMP Strategic Plan. Abbreviations are as follows: SSQ= strategic science question, CMIN= core-monitoring information need, RIN= research information need, and SA=GCDAMP Science Advisors summary questions.

| Glen Canyon Dam Adaptive Management Program (GCDAMP) goal | Adaptive Management Work Group (AMWG) priority science questions and information needs (questions from the Strategic Science Plan (SSP) and MRP in italics)  | Core-monitoring activities   | Experimental activities  | Research and development activities   |
|---|--|--|--|---|
| 1. Food base  | <p>AMWG Priority: 1, 3, and 5</p> <p><i>SSQ 1-5: What are the important pathways that link lower trophic levels with fish and how will they link to dam operations?</i></p> <p><i>SSQ 1-6: Are fish populations, trends, or indicators from fish, such as growth, condition, and body composition, correlated with patterns in invertebrate flux?</i></p> <p><i>SSQ 5-2: Is invertebrate flux affected by water quality (e.g., temperature, nutrient concentrations, turbidity) and dam operations?</i></p>  | <p>Fiscal year (FY) 2009: Review and evaluate aquatic food base monitoring program for core-monitoring status.</p> <p>FY2010–11: Implement aquatic food base core monitoring.</p>  | <p>FY2008–11: Evaluate effects of experimental flows on food web.</p>                    | <p>FY2006–09: Determine carbon budget to understand how energy is exchanged among organisms in the Colorado River; develop monitoring techniques and metrics for key organisms.</p> <p>FY2007: Analyze diet, drift, and predation data.</p>   |
| 2. Humpback chub (HBC) and other native fishes (A.)       | <p>AMWG Priority: 1, 3, and 5</p> <p><i>SSQ 1-1: To what extent are adult populations of native fish controlled by production of young fish from tributaries, spawning and incubation in the mainstem, survival of young-of-year (YoY) and juvenile stages in the mainstem, or by changes in growth and maturation in the adult population as influenced by mainstem conditions?</i></p> <p><i>SSQ 1-4: Can long-term decreases in abundance of rainbow trout (RBT) be sustained with a reduced level of effort of mechanical removal or will recolonization from tributaries and from downstream and upstream of the removal reach require that mechanical removal be an ongoing management action? This question also applies to future removal programs targeting other nonnative species.</i></p> <p><b>CMIN 2.1.2:</b> Determine and track abundance and distribution of all size classes of HBC in the Little Colorado River (LCR) and the mainstem.</p> <p><i>SSQ RIN 3: What life stage(s) of RBT pose the greatest threat to HBC and other native fishes in Grand Canyon? Are the RBT that threaten native fishes in Grand Canyon produced above or below the mouth of the Paria River?</i></p> | <p>FY2007–08: Monitor status and trends of HBC in LCR and mainstem using existing protocols.</p> <p>FY2008: Review and evaluate HBC monitoring program for core-monitoring status in protocol evaluation panel (PEP).</p> <p>FY2009–11: Implement HBC core monitoring.</p> | <p>FY2008–11: Evaluate effects of experimental flows on HBC and other native fishes.</p> | <p>FY2006 and ongoing: Assess stock.</p> <p>FY2007–08: Evaluate gear and sampling efficiency.</p> <p>FY2007–11: Perform a statistical review of existing HBC monitoring protocols and habitat data.</p> <p>FY2007–11: Evaluate protocols for warmwater and coldwater nonnative fish monitoring, removal, and control, and their effects on native fish.</p> <p>FY2009-11: Following a PEP for RBT in FY2008, develop one or more projects investigating piscivory of RBT and origin of RBT in Grand Canyon.</p> |

**Table 1.** Summary of core monitoring, research and development, and experimental activities described in the Monitoring and Research Plan to Support Glen Canyon Dam Adaptive Management Program, Fiscal Years 2007–11. Several long-term experimental activities currently under discussion are not reflected in the table; additional experimental activities will be specified pending the finalization of the LTEP. Activities address Glen Canyon Dam Adaptive Management Program (GCDAMP) goals 1–12 in relation to science questions and information needs. Priority and related strategic science questions are paraphrased from the Draft GCMRC SSP (appendix A). Information needs are paraphrased from the GCDAMP Strategic Plan. Abbreviations are as follows: SSQ= strategic science question, CMIN= core monitoring information need, RIN= research information need, and SA=GCDAMP Science Advisors summary questions.—Continued

| GCDAMP goal                         | Priority science questions and information needs (questions from SSP and MRP in italics)  | Core-monitoring activities                                 | Experimental activities | Research and development activities   |
|-------------------------------------|---|--|-------------------------|---|
| 2. HBC and other native fishes (B.) | <p>AMWG Priority: 1, 3, and 5</p> <p><i>SSQ 1-2: Does a decrease in the abundance of RBT and other coldwater and warmwater nonnatives in Marble and eastern Grand Canyons result in an improvement in the recruitment rate of juvenile HBC to the adult population?</i></p> <p><i>SSQ 1-4: Can long-term decreases in abundance of RBT in Marble and eastern Grand Canyons be sustained with a reduced level of effort of mechanical removal or will recolonization from tributaries and from downstream and upstream of the removal reach require that mechanical removal be an ongoing management action?</i></p> <p><i>SSQ 5-6: Do the potential benefits of improved rearing habitat (warmer, more stable, more backwater and vegetated shorelines, more food) outweigh negative impacts due to increases in nonnative fish abundance?</i></p> <p><b>CMIN 2.4.1:</b> Determine and track the abundance and distribution of nonnative predatory fish species in the Colorado River ecosystem (CRE) and their impacts on native fish.</p> <p><i>SSQ RIN 2: What are the most effective strategies and control methods to limit nonnative fish predation and competition on native fish?</i></p> <p><b>RIN 2.4.3:</b> To what degree, which species, and where in the system are exotic fish a detriment to the existence of native fish through predation or competition?</p> | FY2007–08: Continue mainstem monitoring of fish community. |                         | <p>FY2007–10: Develop and test nonnative fish management plan.</p> <p>FY2007–11: Develop abundance estimation framework that allows scientists to better estimate nonnative fish numbers in mechanical removal reaches.</p> <p>FY2007–10: Develop bioenergetic model to predict changes in fish communities in response to environmental changes.</p> |
| 2. HBC and other native fishes (C.) | <p>AMWG Priority: 1, 3, and 5</p> <p><i>SSQ 1-1: To what extent are adult populations of native fish controlled by production of young fish from tributaries, spawning and incubation in the mainstem, survival of YoY and juvenile stages in the mainstem, or by changes in growth and maturation in the adult population as influenced by mainstem conditions?</i></p> <p><i>SSQ 1-7: Which tributary and mainstem habitats are most important to native fishes and how can these habitats best be made useable and maintained?</i></p> <p><b>SA 1:</b> What are the most limiting factors to successful HBC adult recruitment in the mainstem: spawning success, predation on YoY and juveniles, habitat (water, temperature), pathogens, adult maturation, food availability, competition?</p>  |  |                         | FY2007–10: Review data and literature on HBC in upper basin to see if HBC habitat can be identified, protected, and re-created below Glen Canyon Dam (GCD).   |

# **GCDAMP Goal 1: Protect or improve the aquatic food base so that it will support viable populations of desired species at higher trophic levels**

## **Strategic Science Questions and Information Needs**

Food availability and quality are often important determinants of fish density and condition. For this reason, the MRP seeks to advance goal 1 by addressing discrete scientific questions, information needs, and objectives related to these conditions. Specifically, AMWG priority questions from the KAR were used to frame key SSQs for GCDAMP goal 1. The SSQs that emerged as the focus of monitoring and research activities for goal 1 are listed below:

1. **SSQ 1-5.** What are the important pathways, and the rate of flux among them, that link lower trophic levels with fish?
2. **SSQ 1-6.** Are trends in the abundance of fish populations, or indicators from fish such as growth, condition, and body composition (e.g., lipids), correlated with patterns in invertebrate flux?
3. **SSQ 5-2.** How is invertebrate flux affected by water quality (e.g., temperature, nutrient concentrations, turbidity) and dam operations?

## **Monitoring and Research Activities**

Food base-monitoring and research activities for FY2007–11 carry forward two elements of the overall MRP: core monitoring, and research and development. Food base monitoring and research are discussed in terms of the objectives they are designed to achieve and the individual element of the plan they support.

### **Core-Monitoring Activities**

#### **Monitoring the Aquatic Food Base**

The aquatic PEP (Anders and others, 2001) recommended that “the food base program needs to be critically reviewed because the current level of understanding about the linkages between lower trophic levels and food availability of native fishes is not adequate to interpret food base data in relation to the management goal.” There are two main reasons for this uncertainty: (1) the feeding habits of many fishes have never been studied and (2) the relative contribution of algae and allochthonous carbon to invertebrate and, ultimately, fish production is unclear. In other words, we do not have a good understanding of what constitutes the food base for many fishes and aquatic invertebrates. The new food base research initiative is focused on understanding the linkages that connect lower trophic levels with fish (i.e., What are invertebrates eating? What are fish eating?), quantifying the availability of basal and invertebrate food resources, and documenting the feeding habits of fish throughout the system. Equipped with this knowledge, in FY2009, we intend to develop a monitoring program that is focused on the most important components and drivers of the food base. Activities in this category address SSQ 1-5 and SSQ 5-2.

FY2009–11. Evaluation and implementation of new protocols for monitoring the aquatic food base

Insights from the new food base research initiative (see below) will form the basis for new food base-monitoring protocols that will be evaluated and implemented in FY2009–11. A competitive solicitation process will be used to select cooperators to implement the new monitoring protocols.

## **Research and Development Activities**

### **Trophic Linkages**

Resource managers for native and nonnative fishes need to understand the amounts and quality of aquatic food resources that are available to fishes to direct management actions. In particular, managers need to understand how different flow regimens affect the aquatic food base. Results from previous food base research provide some indication of the food items that are most often consumed by RBT and HBC, but there is very little data on the food base for other fish that are common in the CRE. Further, the relative contribution of allochthonous and autochthonous carbon to invertebrate and, ultimately, fish production remains unclear. This is problematic—an understanding of the carbon sources that contribute to invertebrate and fish production is critical to making informed management decisions, because the supply of autochthonous carbon is strongly affected by dam operations, while the supply of allochthonous carbon is not. Activities in this category address SSQ 1-5, SSQ 1-6, and SSQ 5-2.

FY2005–09. Aquatic Food Base (Project BIO 1.R1.07)

This project was initiated in 2005 to identify energy pathways and quantify basal resources through multiple approaches. Field work on the project began in spring 2006. The project incorporates stable isotope and diet analysis of invertebrates and fish to identify trophic pathways. Flux along trophic pathways will be quantified by calculating invertebrate densities and estimating production and growth, and also estimating rates of food consumption by fish using bioenergetic approaches. Whole-stream metabolism, terrestrial litter inputs from the riparian corridor, and allochthonous inputs from tributary flooding events will be measured to assess basal resources. Lastly, these data will be incorporated into a bioenergetics model for the aquatic ecosystem. Although the focus of the project is on carbon cycling, flux of dissolved and particulate nitrogen and phosphorus is also being studied. Results from this work, scheduled to end in FY2009, will contribute to the development of a core-monitoring program for the Grand Canyon food base in the future.

FY2007. Diet, Drift, and Predation Analysis (Project BIO 1.R3.07)

Rainbow and brown trout diet, food resource availability, and incidence of piscivory were areas of investigation associated with the effort to remove trout from the LCR inflow reach of the Colorado River in Grand Canyon. Some of the tasks associated with these projects have been completed, including field work, laboratory analysis of samples, and data entry. However, the data from these projects have not been assessed for data omission and data entry errors, and they have not been completely compiled into a database. Only preliminary analysis has been conducted to date and the results have not been documented. This project is a 1-year effort for FY2007 and will lead to completion of the database, including quality control and synthesis of

the data in the form of reports and manuscripts. Completion and synthesis of the database provides value to the GCDAMP by increasing understanding of trout diets along downstream reaches of the Colorado River, knowledge that managers need as they evaluate the first project for this goal, above.

## **Long-Term Experimental Activities**

Current studies of the aquatic ecosystem food web are focused on understanding how energy is transferred among organisms, and which energy sources have limited availability. Some GCDAMP stakeholders are also interested in understanding how dam operations affect the amount of primary and secondary production (especially algae, diatoms, and invertebrates) that may be available to native and nonnative fishes as it drifts down the Colorado River in Grand Canyon. Additional work to address these availability questions is being developed by the GCMRC with interested stakeholders. The first implementation of this research is scheduled for FY2008. Additional studies will take place after the LTEP EIS is finalized.

## **Integration**

### **Physical Sciences**

Five of the seven study reaches in the whole-system carbon-cycling project are fine-grained integrated sediment transport (FIST) and integrated water-quality monitoring sites, which will facilitate integration of the physical environment data with the standing mass, distribution, and production of basal resources and invertebrates. The temperature model that is being developed by the Physical Science and Modeling Program will be a valuable tool for estimating systemwide growth rates of algae and invertebrates (temperature is the most important determinant of invertebrate growth rates). Sampling of organic inputs during recent tributary flood events, including a moderate-sized Paria River flood, indicates that organic matter constitutes between 3–6% of the total transported material, with the remainder being sand, silt, and clay. If this relationship holds up, the food base project will be able to estimate organic inputs from tributary flood events based on estimates of sediment inputs obtained by the Physical Science and Modeling Program.

### **Fisheries**

Ongoing fisheries monitoring data on the distribution and relative density of common native and nonnative fishes will be used to determine rates of energy flow to fishes in the system. Where possible, cooperating scientists will also rely on existing fisheries monitoring to obtain the fish stomachs and tissue samples required for gut content and stable isotope analysis, respectively. The analysis of trout diets and other data collected during mechanical removal will provide valuable information on the temporal variability of basal resources and food habits of fish that are outside the scope of the food base research initiative. Further, completing the stomach content analysis of samples taken during the mechanical removal project will help managers evaluate what RBT in the removal reach have been eating and how this may or may not impact HBC entering and exiting the LCR.

## **GCDAMP Goal 2: Maintain or attain viable populations of existing native fish, remove jeopardy from humpback chub and razorback sucker, and prevent adverse modification to their critical habitat**

### **Strategic Science Questions and Information Needs**

The MRP for FY2007–11 seeks to address discrete scientific questions, information needs, and objectives that support maintenance of viable populations of native fish. AMWG priority questions from the KAR were used to frame key SSQs for GCDAMP goal 2. The SSQs that emerged as the focus of monitoring and research activities for goal 2 are listed below. Relevant SPG-prioritized CMINs, RINs, and a summary question posed by the SA (SA 1) are also listed below.

1. **SSQ 1-1.** To what extent are adult populations of native fish controlled by production of young fish from tributaries, spawning, and incubation in the mainstem, survival of YoY and juvenile stages in the mainstem, or by changes in growth and maturation in the adult population as influenced by mainstem conditions?
2. **SSQ 1-2.** Does a decrease in the abundance of RBT and other cold and warm water nonnatives in Marble and eastern Grand Canyons result in an improvement in the recruitment rate of juvenile HBC to the adult population?
3. **SSQ 1-4.** Can long-term decreases in abundance of RBT in Marble and eastern Grand Canyons be sustained with a reduced level of effort of mechanical removal or will re-colonization from tributaries and from downstream and upstream of the removal reach require that mechanical removal be an ongoing management action? This question also applies to future removal programs targeting other nonnative species.
4. **SSQ 1-7.** Which tributary and mainstem habitats are most important to native fishes and how can these habitats best be made useable and maintained?
5. **SSQ 1-8.** How can native and nonnative fishes best be monitored while minimizing impacts from capture and handling or sampling?
6. **SSQ 5-6.** Do the potential benefits of improved rearing habitat (warmer, more stable, more backwater and vegetated shorelines, more food) outweigh negative impacts due to increases in nonnative fish abundance?
7. **SA 1.** What are the most limiting factors to successful HBC adult recruitment in the mainstem: spawning success, predation on YoY and juveniles, habitat (water, temperature), pathogens, adult maturation, food availability, competition?
8. **CMIN 2.1.2.** Determine and track recruitment (identify life stage), abundance, and distribution of HBC in the LCR.
9. **CMIN 2.4.1.** Determine and track the abundance and distribution of nonnative predatory fish species in the Colorado River.
10. **RIN 2.4.3.** To what degree, which species, and where in the system are exotic fish a detriment to the existence of native fish through predation or competition?

11. **SSQ RIN 1.** What habitats and habitat characteristics, if any, will enhance survival, growth, and reproduction of native Grand Canyon fishes, especially HBC, in the mainstem Colorado River?
12. **SSQ RIN 2.** What are the most effective strategies and control methods to limit nonnative fish predation and competition on native fish?
13. **SSQ RIN 3.** What life stage(s) of RBT pose the greatest threat to HBC and other native fishes? Are the RBT that threaten HBC produced above or below the mouth of the Paria River?

**Note:** Razorback sucker (RBS) are not currently regularly observed in Grand Canyon. Ongoing monitoring for native and nonnative fishes may capture this species if it is present or returns to the system.

## **Monitoring and Research Activities**

Activities to support goal 2 range from monitoring to provide decisionmakers with status and trends information on native and nonnative fishes, to research on the habitat preferences of HBC and the effects of modified low fluctuating flows (MLFF) on RBT. Individually, activities can generally be characterized as core monitoring, research and development, or experimental, in keeping with the structure of the MRP; however, when considered together, the activities described below are designed to complement one another and strategically address the myriad factors related to reaching goal 2. Many of the activities described below will be undertaken in partnership with GCDAMP stakeholders, especially the USFWS and the Arizona Game and Fish Department (AZGFD).

### **Core-Monitoring Activities**

#### **Monitoring of Native and Nonnative Fishes**

Monitoring the status and trends of the fish community of the Colorado River in Grand Canyon is integral to assessing the impacts of dam operations on these species and assessing progress towards meeting recovery goals. Monitoring of fishes is led by the GCMRC with GCDAMP partners, especially the USFWS and the AZGFD, to provide managers with information to support management decisions. Varying flow regimens and nonflow actions (especially the mechanical removal of nonnative fishes near the LCR inflow) have been implemented in recent years. Continued monitoring is needed to evaluate whether these actions have been beneficial or detrimental to native and nonnative fishes. Because of its Federal endangered status, the HBC is often the focus of Grand Canyon fish monitoring. HBC monitoring will be conducted in accordance with the standards specified in the HBC recovery plan ((USFWS, 2002). Current monitoring will be maintained in FY2007 and FY2008, building on the current long-term dataset for HBC and other fish species. Monitoring results will also be used to develop core monitoring for HBC, the subject of a PEP scheduled for FY2008. The recommendations from this PEP will be implemented in FY2009 and beyond. The primary questions and information needs addressed by these activities are SSQ 1-1, SSQ 1-2, and CMIN 2.1.2.

FY2007–08. Little Colorado River Humpback Chub Monitoring Lower 15 km (Project BIO 2.R1.07)

This monitoring of the known spawning tributary of HBC in Grand Canyon will be led by the USFWS. Sampling is conducted with hoop nets during four annual trips, two in the spring and two in the fall, as a continuation of the LCR HBC stock assessment program initiated in fall 2000. These trips will occur in March, April, September, and October, and provide spring and fall abundance estimates of HBC in the LCR. Tags deployed in fish during fall and spring LCR trips may be available for later recapture during mainstem activities. In addition to the short-term estimates that these sampling trips will support, the monitoring provides continued data collection to advance the age-structured mark recapture (ASMR) open population model for HBC.

FY2007–08. Little Colorado River Humpback Chub Monitoring Lower 1,200 m (Project BIO 2.R2.07)

This monitoring maintains a dataset that has been conducted annually, with few exceptions, since the 1980s. HBC are monitored with hoop nets near the mouth of the LCR. The monitoring is led by the AZGFD.

FY2007–08. Humpback Chub Monitoring Above Chute Falls (Project BIO 2.R3.07)

This project, led by the USFWS, monitors the population of HBC found above Chute Falls (river mile 9.1), a frequent if inconsistent barrier to upstream fish movement in the LCR. HBC were translocated above the falls in 2003, 2004, and 2005 and presented evidence of spawning (production of young fish) in 2005. Untagged adult fish were captured in 2006, indicating that limited movement above the falls is possible.

FY2007–08. Monitoring Mainstem Fishes (includes below Diamond Creek) (Project BIO 2.R4.07)

This project combines elements of multiple projects from previous years, including sampling of the fish community in the Colorado River mainstem between Lees Ferry and Diamond Creek and from Diamond Creek to Pearce Ferry. The timing coincides with three of the four lower 15 km LCR sampling events to achieve concurrent sampling, consistent with reviewer recommendations. While HBC sampling is the focus of this work, information on other native and nonnative fishes is also gathered. The full mainstem sampling events will be conducted once in spring and once in fall to provide biannual snapshots of the fish community. The mainstem monitoring will also detect changes in nonnative fish populations that will be used to inform future nonnative control efforts.

FY2007–10. Nonnative Control Planning and Nonnative Control Pilot Testing (Project BIO 2.R5.07 and Project BIO 2.R6.07)

One of the biotic factors thought to be limiting to native fishes is nonnative fish, which may compete with native fish for food and prey on young native fish. This threat was addressed during FY2003–06 with the mechanical removal of RBT and other nonnative fish using boat electrofishing. With warming of the Colorado River in Grand Canyon, the nonnative fish species posing the greatest threat to natives may change to species more adapted to warmer water. The threats from nonnative species will be addressed in a comprehensive nonnative control plan to be developed in FY2007–10. Pilot projects will be implemented, assessed, and refined. The

DIDSON camera may be deployed with some gear types to evaluate its efficacy. Questions and information needs addressed by these projects are SSQ 1-4, SSQ 5-6, CMIN 2.4.1, SSQ RIN 2, and RIN 2.4.3.

## Modeling Populations

As managers and scientists strive to conserve the natural resources of Grand Canyon, it is important to characterize the size and trend of the resident HBC population over time. The GCMRC has taken the lead in estimating population size and trend and will continue to lead this effort in the future. Population characterization and modeling is dependent on some of the other projects described above, especially ongoing monitoring. Associated projects include development of a bioenergetic model of the Grand Canyon fish community to predict changes in response to the changing environment, and development of abundance estimation procedures for nonnative fishes. Analysis of data collected in the field informs decisions on sampling design and gear selection. Questions and information needs addressed by these projects are SSQ 1-2, SSQ 1-4, SSQ 5-6, CMIN 2.4.1, and RIN 2.4.3.

### FY2007–11. Stock Assessment of Native Fish in Grand Canyon (model development) (Project BIO 2.R7.07)

To provide the most current information on HBC status and trend information, the GCMRC ASMR database will be updated annually with the most recent data from routine monitoring. Following this update, the database will be reanalyzed using (where appropriate) both open and closed ASMR-based abundance estimators. We will rely on ASMR models and other appropriate models to determine trends in HBC abundance and recruitment. Finally, we will evaluate the applicability of similar techniques as described above to assessing stocks of flannelmouth sucker (FMS) and bluehead sucker (BS).

### FY2007–11. Abundance Estimation Procedures (Project BIO 2.R8.07)

Currently, the traditional Zippin abundance estimator is used to estimate the abundance of nonnative fish (primarily RBT) in the mechanical removal reaches of the Colorado River. Though accepted and widely applied, this estimator makes the strict assumption that the vulnerability of fish among depletion passes is constant. Because large changes in turbidity are commonly observed within and among removal trips, this assumption is questionable. A more contemporary Bayesian estimation framework allows relaxation of this assumption if the relationship between a covariate (e.g., turbidity or sediment concentration) and vulnerability can be estimated. Additionally, this framework may allow more efficient use of the available data by allowing model-based aggregation of site-specific estimates. The Bayesian Inference using the Gibbs sampler program (BUGS) will be used to fit models to our removal data.

### FY2007–10. Bioenergetic Modeling (Project: BIO 2.R9.07)

We will construct an ecopath model (<http://www.ecopath.org/>) using data available from previous studies conducted in Grand Canyon as well as the relevant scientific literature. Of particular importance will be the diet data collected during the mechanical removal project.

## Monitoring Technology Research

The native fish population of Grand Canyon, especially HBC, is handled regularly as part of efforts to understand the population size status and trends and also during mechanical removal. Electroshocking and netting of fish to evaluate populations can cause stress and reduce the growth of these animals, especially when they are handled repeatedly (e.g., Paukert and others, 2005). Negative effects of capture, especially of endangered fishes, have led researchers to seek less invasive methods such as alternative gears and remote monitoring technologies. Tagging technologies that could reduce repeated handling of fishes need to be evaluated for their effectiveness in Grand Canyon. Acoustic imaging technologies show promise for describing distribution/habitat selection of native fishes. Research of some alternative monitoring technologies will be conducted beginning in FY2007. The question addressed by these projects is SSQ 1-8.

### FY2007–09. Trammel Net Effects (Project BIO 2.R12.07)

Trammel nets have been used extensively to capture native fishes in the Colorado River, but have also been implicated in the injury of fish. This project provides partial support to a Northern Arizona University (NAU) graduate student to investigate the impacts of these nets on fish. The results of the student's research will be used to evaluate this gear type for future studies of native fishes in Grand Canyon.

### FY2007–09. Remote PIT Tag Reading (Project BIO 2.R13.07)

Fisheries researchers in Grand Canyon (and around the world) inject fish with a unique electronic identifying code in a PIT tag. The standard method for reading these tags is to check for the presence of a PIT tag upon capture of an individual fish, but remote PIT tag reading technologies are being developed. Experimentation with the use of remote antennae to read PIT tags will be conducted. The study area will focus, at least initially, on the LCR confluence with the Colorado River.

### FY2007–09. Test Sonic Tags (Project BIO 2.R14.07)

Experimentation with sonic tags will be led by GCMRC and AZGFD personnel, working closely with the product's manufacturer. Initial efforts will focus on capturing nonnative fish, implanting them with tags, and releasing them to see if the equipment is effective in the Colorado River.

### FY2007–09. Test DIDSON Camera (Project BIO 2.R15.07)

The DIDSON camera is owned by Reclamation and housed in Denver, Colo. The camera uses acoustic technology to produce an underwater image. It is especially effective in low light and turbid conditions as are common in the Colorado River. The camera's operator will be accompanied by GCMRC personnel on a river trip to test which habitat types can be sampled most effectively and to determine if fish aggregations can be identified.

## **Research and Development Activities**

### **Habitat**

The published assumptions regarding which habitats are optimum and available for different life stages of HBC need to be tested, but they could serve to direct long-term monitoring, population modeling, and the selection of flow regimens. To the extent possible, the characteristics of habitats that are most important to native fishes (physical, water quality), particularly in the mainstem Colorado River, need to be identified. Habitat characteristics needed by YoY and juvenile HBC are most important to identify and protect because of the endangered status of this species. GCMRC will develop a project to use existing and new data to investigate habitat use by young HBC and other native fishes, especially in the mainstem Colorado River. GCMRC intends that SSQ RIN 1 will be addressed through modeling habitat usage, mining the available data for information on HBC captures, and developing one or more new collection efforts to help understand the habitat use by and fate of subadult HBC and other native fishes.

The questions addressed by the project below are SSQ 1-1, SSQ 1-7, and SA 1. A PEP for RBT will be conducted in FY2008. The issues of RBT predation on HBC and other native fishes (SSQ RIN 3) will be discussed with the panelists with the specific aim of developing one or more projects that investigate the threat to native fishes from RBT piscivory and where Grand Canyon RBT are produced.

FY2007–10. Native Fishes Habitat Data Analysis (Project BIO 2.R11.07)

The GCMRC will review existing data and available literature and information from the upper basin on HBC habitat usage and preferences to see if such habitats can be identified from available data. A multivariate statistical method for linking environmental variables to fish populations will be tested for its value in defining important habitat characteristics, including river flows, water-quality characteristics, and physical habitat.

## **Long-Term Experimental Activities**

### **Evaluating Effects of Experimental Flows on Fish**

The habitats used by native fishes have been the subject of substantial research, but the research remains scattered in many different references. One of the shortcomings of this research is a lack of quantification of existing habitat types and how those habitat types change over time. To address this information need, GCMRC staff and cooperators will try to detect changes in the abundance and distribution of different shoreline habitat types, especially sandbars and backwaters, in the Colorado River (Data Acquisition, Storage, and Analysis Program [DASA] 12.D6.07). In terms of fish, knowledge of the distribution, abundance, and change potential of these habitats in the mainstem will help scientists evaluate the mainstem's potential to support young HBC under various flow regimes. This project will build on the baseline dataset of shoreline habitat for six habitat types at the 8,000-cfs elevation developed from 2000 data. Three other remote-sensing datasets from 2002–05 data will be used to extend the time series for a 5-year period. Using data taken in different years will extend the dataset to include higher elevation habitats up to 45,000 cfs. Higher elevation information will allow for better correlation of existing fish collection information with a variety of flows.

## **Integration**

Food base research is closely associated with the fish community in Glen and Grand Canyons because most native and nonnative fish species depend on primary and secondary production for sustenance. The current food base study includes a component that integrates carbon flow through the system, including fishes. Monitoring of the native and nonnative fish populations will provide additional information for evaluating the results of the food base study; for example, flux in fish populations can be correlated with the flux of the food base to evaluate the importance of primary and secondary production for fishes.

Monitoring and characterization of the fish community of Grand Canyon will be integrated with monitoring and modeling of physical habitat and water-quality parameters, especially in relation to various GCD release regimens. Additional details of integration strategies and products are provided above and in the FY2007 annual work plan.

### **GCDAMP Goal 3: Restore populations of extirpated species, as feasible and advisable**

Goal 3 is not currently a GCDAMP priority goal; however, the goal is part of the NPS and USFWS long-term resource management objectives. If goal 3 becomes a higher priority for GCDAMP in the future, the feasibility of reintroducing the target extirpated species will be investigated first.

The knowledge gained from GCMRC monitoring and research on key ecosystem drivers—the operation of the GCD, riparian zone health and function, and water quality—will be useful to assess the steps necessary to reintroduce specified extirpated native fish, mammals, and amphibians into the river ecosystem. As the CRE improves and changes, the NPS, USFWS, and the AZGFD will, in cooperation with the GCDAMP, prioritize any reintroduction efforts.

## **GCDAMP Goal 4: Maintain a naturally reproducing population of rainbow trout above the Paria River, to the extent practicable and consistent with the maintenance of viable populations of native fish**

### **Strategic Science Questions and Information Needs**

Monitoring of the RBT population above the Paria River is an important activity for evaluating population status and trends to determine whether they are meeting goal 4. Therefore, monitoring of this population is to continue during FY2007–11. Monitoring data will be used to support a PEP scheduled for FY2007. The fate of trout eggs and very young fish in response to dam operations will be the subject of continuing research in FY2007 and FY2008. The primary SSQ, CMINs, and RIN addressed by both projects are as follows:

1. **SSQ 3-6.** What GCD operations (ramping rates, daily flow range, etc.) maximize trout fishing opportunities and catchability?
2. **CMIN 4.1.2.** Determine annual proportional stock density of RBT in the Lees Ferry reach.
3. **CMIN 4.1.4.** Determine annual standard condition (Kn) and relative weight of RBT in the Lees Ferry reach.
4. **RIN 4.1.1.** What is the target proportional stock density (i.e., tradeoff between numbers and size) for RBT in the Lees Ferry reach?

### **Monitoring and Research**

#### **Core-Monitoring Activities**

Monitoring of the RBT population above the Paria River will continue to document population changes and condition factors. Current monitoring results and those from previous years will be used to inform the FY2007 PEP, which, in turn, will be used as guidance for core monitoring of RBT population above the Paria River.

FY2007. Status and Trends of Lees Ferry trout (Project BIO 4.M1.07)

Electrofishing as a sampling technique to estimate the biological parameters used to assess fishery status and trends. Electrofishing provides information on size composition, relative abundance (catch per minute as a surrogate for population size), and condition (length-weight relationships). Samples are collected for whirling disease examination. The project addresses SSQ 3-6, CMIN 4.1.2., and CMIN 4.1.4.

FY2007. RBT Redds and Larvae (Project BIO 4.E1.07)

Analysis of redd (nest) production, egg production, and larval survival will be continued in FY2007 to determine population responses to flows and to inform the PEP process. Information from this project and monitoring helps managers and peer reviewers to address RIN 4.1.1, as well as SSQ 3-6, CMIN 4.1.2, and CMIN 4.1.4.

## **Research and Development Activities**

The aquatic food base research project described under goal 1 will support efforts to determine the amount and quality of food available for trout.

## **Long-Term Experimental Activities**

The aquatic food base project will monitor fish population and habitat responses to various experimental flow regimens. The results of monitoring will contribute to understanding what flow regimens best support and maintain the RBT present below GCD.

## **Integration**

The aquatic food base research project described under goal 1 helps provide evaluation of the amount and quality of food available for trout.

## **GCDAMP Goal 5: Maintain or attain viable populations of Kanab ambersnail**

### **Strategic Science Questions and Information Needs**

Managers and scientists continue to investigate the highly variable KAS population in Grand Canyon. Population size and habitat measurements reveal that both snail numbers and habitat availability can vary dramatically; therefore, the natural, acceptable population and habitat size variability remains undefined. What amount of variability is natural (the natural condition that managers are trying to achieve) will be one of the prime questions addressed by the USFWS as part of their status review of this species in 2006 and 2007. Another important issue for USFWS to consider will be the taxonomic status of the Vaseys Paradise population. This population was included in other populations in a 2007 genetics study under contract with the GCMRC at the University of Arizona. The GCMRC will be closely involved in providing science support to the USFWS during their review.

GCMRC in cooperation with partner agencies will continue to address the following CMINs for the KAS:

1. **CMIN 5.1.1.** Determine and track the abundance and distribution of KAS at Vaseys Paradise in the lower zone (below 100,000 cfs) and the upper zone (above 100,000 cfs).
2. **CMIN 5.2.1.** Determine and track the size and composition of the habitat used by KAS at Vaseys Paradise.

### **Monitoring and Research Activities**

#### **Core-Monitoring Activities**

Population and habitat monitoring methods for KAS continue to be refined. Working closely with AZGFD and NPS, GCMRC is providing logistics support and data analysis for ongoing monitoring. The species status review conducted by the USFWS in 2006–07 will provide important guidance for determining what constitutes core monitoring for this species. This guidance will be subject to review by GCDAMP committees and the NPS when determining their core-monitoring needs. Monitoring activities address CMIN 5.1.1 and CMIN 5.2.1.

FY2007–11. Monitoring Kanab Ambersnail (Project: BIO 5.R1.07)

Habitat surveys at Vaseys Paradise include surveying the total area of the habitat and individual patches of vegetation within the habitat. Areas are determined using traditional land-survey methods. Habitat surveys are conducted in the spring and fall of each year. Within each designated patch, the cover and heights of dominant plant species are recorded, as are variables associated with soil moisture. Snail densities are determined by randomly sampling areas within vegetation patches. Snail densities are extremely variable seasonally and among vegetation patches. Consequently, confidence intervals around subsequent population estimates are large and considered to be statistically unreliable, so more emphasis is needed with regard to sampling emphasis and approaches. The project addresses CMIN 5.1.1 and CMIN 5.2.1.

## Research and Development Activities

### Testing Alternative Methods

Surveying in Vaseys Paradise to determine the extent of the habitat can be invasive. Remote technologies like oblique orthorectified imagery and land-based LiDAR might be used to determine area cover and plant height without the need to step into the habitat. Alternative methods will be tested beginning in FY2007 to assess potential survey and monitoring approaches for incorporation into long-term monitoring. Depending on the results of these tests, conducted in conjunction with monitoring, additional projects could be identified in future fiscal years.

### Genetic Research

Current genetics research of the *Oxyloma* species has been supported by GCDAMP funds through the GCMRC. Results are expected in 2007 and may contribute to the species status review.

## Long-Term Experimental Activities

### Experimental Flows Population Monitoring and Habitat Salvage

In November 2004, before the 2004 experimental BHBF, the GCMRC and the AZGFD temporarily removed habitat patches that were determined to be subject to scouring. These patches were moved above the inundation level and then returned to their original locations. The habitat survived the temporary removal and habitat loss was successfully averted during the high-elevation flow. Population response to this action suggests that removal and replacement of habitat patches can be conducted during the period of low flows before and following high-flow tests, respectively. To ensure confidence in this result, monitoring of this technique, and especially its safety for the KAS population, should accompany future BHBFs.

## Integration

The KAS monitoring trips are conducted in conjunction with river trips that sample backwater habitats for small-bodied fishes with seines. This arrangement allows researchers to monitor two very different species and habitats with a single river trip.

## **GCDAMP Goal 6: Protect or improve the biotic riparian and spring communities, including threatened and endangered species and their critical habitat**

### **Strategic Science Questions and Information Needs**

The riparian and spring vegetation communities of Grand Canyon are components of many other resources, including vertebrate habitats, organic inputs into the river, sediment transport, recreation sites, and cultural resources. Understanding how dam operations and other factors, especially climate, affect the vegetation communities requires understanding the existing vegetation communities and how they change. The projects planned under this goal are designed to document and model the vegetation communities and how they change with the goal of developing remote monitoring and modeling capabilities to inform management needs.

Monitoring and research activities related to goal 6 address the following SSQs and CMINs:

1. **SSQ 2-1.** Do dam controlled flows affect (increase or decrease) rates of erosion and vegetation growth at archaeological sites and TCP sites, and if so, how?
2. **SSQ 4-2.** How important are backwater and vegetated-shoreline habitats to the overall growth and survival of YoY and juvenile native fish? Does the long-term benefit of increasing these habitats outweigh short-term potential costs (displacement and possible mortality of young HBC) associated with high flows?
3. **CMINs 6.1.1, 6.2.1., 6.5.1, and 6.6.1.** Determine and track the abundance, composition, distribution, and area of terrestrial native and nonnative vegetation in the CRE.

### **Monitoring and Research Activities**

#### **Core-Monitoring Activities**

Riparian vegetation monitoring requires systemwide assessment of vegetation change at the broad scale (e.g., new high-water zone) as well as at the local scale (e.g., plot data at 25,000 cfs). While knowing how much vegetation exists in the river corridor is useful, it is equally useful to know how the species that make up the vegetation may be changing. Changes in riparian vegetation are associated with dam operations (Stevens and others, 1995; Kearsley and others, 2006) and can include the propagation of exotic species like tamarisk (Porter, 2002). Yearly transects can detect changes among herbaceous species, including invasives, while remotely sensed data collected at 5-year intervals can assess changes in overstory wood species that change more slowly. Monitoring in this way provides data across temporal and spatial scales. In FY2007, this work is being developed as a core-monitoring project and will be reviewed by a PEP. These monitoring activities address SSQ 2-1, CMIN 6.1.1, CMIN 6.2.1, CMIN 6.5.1, and CMIN 6.6.1.

FY2007–08. Vegetation Mapping (Project BIO 6.R1.07)

FY2007–11. Vegetation Transects (Project BIO 6.R2.07)

These two field-based projects are designed to complement one another. Annual monitoring that uses vegetation transects (Project BIO 6.R2.07) associated with specific stage elevations records species diversity, richness, and cover. The changes in vegetation parameters that this monitoring detects is relevant to perennial and annual herbaceous species like bunch grasses, marsh species, and invasive species that can change on an annual basis. Vegetation mapping (Project BIO 6.R1.07) utilizes overflight digital imagery (a product of the DASA Program) to quantify larger scale area changes (e.g., expansion of arrowweed patches, or extent and type of vegetated shoreline). Analysis of change detection in the vegetation mapping project would incorporate the annual transect survey results to help explain patterns of change occurring over a 5-year time frame. The two projects complement each other because they provide information about changes in riparian habitat at different ecological scales that may affect other riparian community constituents like invertebrate biomass and riparian bird abundance.

## Research and Development Activities

Our understanding of how riparian vegetation changes as a result of dam operations is well developed for marsh species (see Stevens and others, 1995). The authors related decadal changes in operations, geomorphic reach, and distance from the dam to area cover and species composition. Our knowledge regarding this community was reaffirmed during the two knowledge assessment workshops, which are summarized in Melis and others (2006). However, as one moves upslope from the channel, our understanding of how operations influence vegetation change is less conclusive. As a result of the vegetation transects completed from 2000 to 2004, we do know that dam operations affect vegetation cover, richness, and diversity up to the 35,000-cfs river stage elevation, while the local environment appears to affect vegetation above this elevation. We do not know how short-duration high flows (discharges greater than 31,000 cfs), may change riparian vegetation. This topic will be considered within the scope of the vegetation synthesis.

FY2007–11. Vegetation Synthesis (Project BIO 6.R3.07)

The vegetation synthesis project will use mapping and monitoring results to test mechanisms that affect riparian vegetation establishment and expansion, including rates of change and potential colonization sites. The synthesis seeks to address knowledge gaps identified by the KAR. For example, the KAR revealed that there was some certainty about the relationship of marsh community development and flows for the CRE, but that this certainty decreased as one progressed upslope. Additionally, the KAR found a need for an understanding of the integrated role of riparian vegetation with other resources (e.g., aquatic and cultural resources). A synthesis is a step toward meeting these needs and will be implemented in two parts. Part I (FY2007–09) will address local processes and systemwide change, and Part II (FY2009–11) will integrate faunal and cultural components. This project addresses SSQ 1-5 and SSQ 3-2.

## Long-Term Experimental Activities

Experiments associated with riparian vegetation will be curtailed until Part I of the vegetation synthesis is completed in FY2009. An experiment associated with riparian vegetation that could be subsequently implemented would be to remove vegetation that is subject to inundation during high flows, including low-growing limbs, to determine the effect of reduced vegetation on sediment transport and deposition, and to observe colonization rates in understory and open-beach areas. The colonization rates would examine how native versus introduced species compete and occupy newly available space. The results would be used to test hypotheses generated in the synthesis. In the interim, annual monitoring correlated with stage variation will provide a general picture of vegetation response to the changes in operations associated with long-term experimental planning from FY2007–11.

## Integration

Riparian vegetation is a critical interface between aquatic and terrestrial environments around the world. In the CRE, the vegetation serves as a host for invertebrates, provides breeding and foraging habitat for birds and cover in the heat of the day, and may be harvested for cultural uses. Changes in the composition or structure of riparian vegetation like the expansion of an exotic species may alter these interactions. Riparian vegetation regulates nutrient exchange between the land and water. For example, leaf litter is a terrestrial carbon source that may influence in-stream invertebrate production. The relative importance of terrestrial carbon in the aquatic food web is being addressed in part through the food base initiative. The linkage could be further defined through studies that focus on terrestrial productivity and processes. Again, changes in abundance or kind of riparian carbon sources may influence aquatic productivity processes. In addition, a better understanding of the influence of vegetation on cultural resources is needed (which was noted in the KAR). Through a combination of monitoring, synthesis, and field research, the Biology Program will improve the understanding of the role riparian vegetation plays in influencing other resources.

## **GCDAMP Goal 7: Establish water temperature, quality, and flow dynamics to achieve the GCDAMP ecosystem goals**

### **Strategic Science Questions and Information Needs**

Recognizing the importance of the qualities of water released from GCD, the GCMRC seeks to better understand how water-quality conditions in Lake Powell interact with downstream quality of water and aquatic resources below the dam. This will be addressed with a program of monitoring and modeling both in Lake Powell and downstream.

In 2004, the AMWG identified several priority questions, one of which relates directly to downstream quality of water, particularly water temperature below GCD: AMWG Priority 3: What is the best flow regime?

During the 2005 knowledge assessment workshops, biological scientists also identified uncertainty about achieving fishery and food web objectives related to downstream water quality and temperature. As a result, the scientists formulated several key SSQs for GCDAMP goal 7 around those uncertainties. The most critical SSQs that emerged as the focus of monitoring and research activities for goal 7 are as follows:

1. **SSQ 3-5.** How is invertebrate flux affected by water quality (e.g., temperature, nutrient concentrations, turbidity) and dam operations?
2. **SSQ 5-1.** How do dam release temperatures, flows (average and fluctuating component), meteorology, canyon orientation and geometry, and reach morphology interact to determine mainstem and nearshore water temperatures throughout the CRE?
3. **SSQ 5-3.** To what extent do temperature and fluctuations in flow limit spawning and incubation success for native fish?
4. **SSQ RIN 4.** What are the effects of ramping rates on sediment transport and sandbar stability?

As part of the GCDAMP strategic plan, several CMINS for measurements of downstream flow and water temperature, as well as the quality of water leaving GCD, were identified. The key CMINS related to goal 7 are as follows:

1. **CMIN 7.1.1.** Determine the water-temperature dynamics in the mainstem, tributaries (as appropriate), backwaters, and nearshore areas throughout the CRE.
2. **CMIN 7.2.1.** Determine the seasonal and yearly trends in turbidity, water temperature, conductivity, DO, and pH, changes in the mainstem throughout the CRE.
3. **CMIN 7.3.1.** What are the status and trends of water quality releases from GCD?

Monitoring of stage and discharge below GCD provides a means for determining when dam operations are in compliance with the 1996 ROD, as well as when departures occur under emergency criteria. Owing to the fact that suspended-sediment measurements are usually considered to be a component of the quality-of-water monitoring project, the CMINS associated with goal 8 for sediment are also tied to monitoring of downstream quality of water (see goal 8, this report).

## Monitoring and Research Activities

Monitoring and research activities related to goal 7 are carried out by the IQW project and involve Lake Powell, the tailwater of GCD, and the water downstream of GCD. All of the activities related to goal 7 carry forward one or more of the three elements of the MRP: core monitoring, research and development, and long-term experimentation. Individual monitoring and research activities will be discussed in terms of the element of the plan they support.

### Core-Monitoring Activities

#### Upstream Quality of Water Monitoring of Lake Powell and Glen Canyon Dam Tailwater

Processes within Lake Powell, climate changes in the upper Colorado River Basin, the structure of GCD, and dam operations affect the quality of water released from GCD to the CRE in Grand Canyon. Temperature, dissolved oxygen concentrations, nutrient concentrations, biological composition, and other characteristics of GCD releases can have a profound effect on the aquatic ecosystem below the dam. Activities in this category are designed to address SSQ 3-5, SSQ 5-1, and SSQ 5-3.

#### *FY2007–11. Quality-of-Water Monitoring of Lake Powell and the Glen Canyon Dam Tailwater (Project BIO 7.R1.07)*

Water quality in Lake Powell, including temperature, makes a fundamental contribution to the aquatic environment downstream of GCD. This monitoring project maintains a 40-year database of water-quality information that managers can use to understand the aquatic environment available to organisms downstream. These data are being combined with other data to support downstream thermal modeling. A data report that includes status and trends of parameters and identification of recurring patterns will be produced by the GCMRC in FY2007. This report will inform further analysis in future years concerning reservoir processes, climatic versus operational effects, and suitability of the released water for downstream resources. The results of the ongoing monitoring will be a fundamental resource for an expert PEP anticipated in FY2009. The PEP will look critically at the current protocols and recommend any necessary changes.

#### Downstream Quality of Water Monitoring

Suspended-sediment-transport data for both sand and finer particles are analyzed and used to update managers about the status of suspended-sediment flux between the two major tributaries (influx) and export to upper Lake Mead (efflux). Measurements and modeling estimates for tributary sand influx and main channel efflux are used to support experimental flow triggers related to BHBFs and to evaluate other research flows, such as alternative fluctuating operations and stable flows. Temperature, flow, and stage data are also available for use by scientists in assessing habitat characteristics for aquatic organisms. This effort addresses SSQ 5-1.

*FY2007–11. Downstream Integrated Quality-of-Water Monitoring (below Glen Canyon Dam) (Project PHY 7.M1.07)*

The downstream IQW monitoring project focuses primarily on monitoring but also supports research on experimental flows, including BHBFs. There are several general components to the monitoring strategy for goal 7 relating to the downstream IQW project:

- Monitor and report real-time data of release pattern of GCD (stage and discharge, as measured at the Colorado River gage near Lees Ferry and key points downstream)
- Monitor and report real-time quality-of-water data for downstream segments of the CRE that focus on manager needs and supports modeling below GCD (temperature, specific conductivity, and other characteristics in the main channel and selected tributaries)
- Monitor and report estimates for (measurements and modeling) sand and silt/clay volumes (with grain sizes) delivered by major and lesser tributaries below GCD (ecosystem's influx of fine sediments)
- Monitor and report estimates for (measurements and modeling) sand and silt/clay volumes (and grain sizes) transported by the Colorado River downstream below GCD (ecosystem's efflux of fine sediments)
- Monitor to support experimental flows; as need arises, collect additional similar data in support of experimental flows released from GCD

## Research and Development Activities

### Advanced Development of Downstream Flow, Temperature, and Sediment Modeling

*FY2007–08. Monitoring Support Linked with Integrated Quality-of-Water Monitoring (Project PHY 7.R1.07)*

Several modeling efforts and related research activities are planned for the 2007–11 monitoring and research period:

- Ongoing development and verification of thermal and sediment-transport models below GCD as well as user interfaces and World Wide Web access to data
- Applications of sediment and thermal-modeling simulations for science planning support
- Interdisciplinary cooperation between scientists modeling water quality and food web researchers working on the development of nutrient monitoring and mass balance
- Evaluation of use of hydroacoustic instrumentation for continuous monitoring of organic drift in the Lees Ferry reach

As part of science efforts between 2007 and 2011, the GCMRC will continue development of a downstream model for temperature (initiated in 2006). Temperature monitoring along the main channel is proposed to be expanded to include seasonal measurements in selected nearshore environments, such as backwaters (return-current channel) within Marble

and eastern Grand Canyons. These data support ongoing development of a downstream thermal model for the main channel and associated nearshore habitats of importance to aquatic organisms and fish.

During 2007 and 2008, GCMRC scientists and cooperators conducting research on nutrient dynamics related to the ecosystem's aquatic productivity and the quality-of-water project are scheduled to continue collaborative efforts to define future monitoring activities. One objective of the food web research is to help the GCMRC identify elements of downstream monitoring that might be of interest to managers. Strategies for expanding downstream quality-of-water measurements and integrating new protocols with existing measurements will be explored during the remainder of the food web research. Use of acoustic backscattering data for estimating drifting organic matter leaving the Lees Ferry reach was attempted as a pilot study in 2005. Preliminary evaluation of this approach shows promise and is the motivation for more detailed field activities between the IQW staff and GCMRC aquatic scientists in FY2007 and beyond.

## Long-Term Experimental Activities

### Experimental Flow Support

As need arises, the IQW project will collect additional quality-of-water and suspended-sediment data in support of experimental flows released from GCD, including future BHBF tests. Depending upon the suite of flow tests in the long-term experimental design, additional experimental studies, such as alternative fluctuating flows, might also be the focus of field measurements, flume experiments, and modeling simulations to address the above science questions related to fine sediment dynamics, conservation of sandbars, etc.

The experimental design for future BHBF studies has not been fully determined, but is likely to focus on replication of a high-flow release of similar duration to the experiment conducted in 2004 (41,000 to 45,000 cfs for approximately 2 days) under sand-enriched conditions from the Paria and Little Colorado Rivers. The logic for additional BHBFs under sand-enriched conditions similar to those that preceded the 2004 experiment is described in the next section related to goal 8 (sediment).

Additional flow and sediment studies are most likely to focus on alternative fluctuating flows (SSQ RIN 4), possible stable flows, or even thermally modified releases from GCD by the end of the monitoring and research period.

## Integration

Interdisciplinary studies between the IQW project and other resource areas have great potential and have been highly productive, resulting in high-resolution data streams for temperature, conductivity, and suspended-sediment data throughout the CRE. Integration will be necessary to answer most of the SSQs associated with AMWG priority 5. For example, dissolved oxygen data measured in the tailwater below the dam and in Lake Powell are of special interest to fisheries biologists and managers in the Lees Ferry reach. Temperature and suspended-sediment data are particularly important to scientists working on problems of fishery habitat use and productivity above and below the Lees Ferry reach. River discharge and associated downstream stage data are important for understanding nutrient spiraling and habitat conditions

throughout the main channel of the ecosystem. The evolving state of the fine-sediment mass balance throughout the ecosystem influences efforts to restore and maintain beaches of interest to managers and scientists for their roles in the aquatic and terrestrial environments. Continued in situ preservation of cultural resource sites depends upon nearshore beach habitats being sufficiently nourished by new tributary sand supplies (presumably through effective BHBF implementation) to contribute to wind-transported sand into arroyos and other geomorphic settings where archaeological sites have eroded.

During the monitoring and research period of FY2007–11, new efforts will be made to link core monitoring within the downstream IQW project to food web, fishery, recreation, and archaeological science projects. Special emphasis will be placed on the collection of temperature data that supports improved modeling capabilities for predicting downstream water temperature in the main channel and nearshore habitats. These nearshore data will be collected within the context of seasonal field activities conducted within the fishery, food web research trips, and at sites where those science efforts are already being focused.

The primary objective for promoting use of the IQW core-monitoring data to achieve greater integrated science will be not only to collect these data, but to make them readily accessible to other cooperating scientists and managers so that they can be integrated into focused research and development, as well as experimental research efforts. Historical temperature, flow, and sediment data will be used also in updating and advancing the Grand Canyon conceptual model developed in the late 1990s. Conceptual modeling workshops held during 2007–11 will have access to quality-of-water data from both Lake Powell and downstream IQW efforts.

Sand beach mapping and change detection studies, scheduled for 2007 and beyond, will also have the advantage of using the continuous fine-sediment mass balance core-monitoring data to evaluate sandbar area, volume, and grain-size changes. These changes are being identified over the period 1999–2009, as airborne, remote-sensing missions capture imagery of ecosystem shorelines. With these core-monitoring data for fine-sediment flux, scientists and managers may better evaluate the relationship between dam operations (including BHBF tests) and physical habitat responses associated with sandbars throughout the river corridor.

## **GCDAMP Goal 8: Maintain or attain levels of sediment storage within the main channel and along shorelines to achieve Adaptive Management ecosystem goals**

### **Strategic Science Questions and Information Needs**

Recognizing that achieving and maintaining a sufficient level of sandbars and related habitats is a long-term goal, the MRP is addressing the discrete scientific questions, information needs, and objectives required to attain it in time. In 2004, the AMWG identified several priority questions, including priority question 4, which relate directly to sediment: What is the impact of sediment loss, and what should we do about it?

In addition, during the 2005 knowledge assessment workshops, sediment scientists also identified uncertainty about achieving sandbar conservation objectives and posed key SSQs for GCDAMP goal 8 around those uncertainties. The most critical strategic science questions that emerged as the focus of monitoring and research activities for goal 8 are

- **SSQ 4-1.** Is there a “Flow-Only” operation (i.e., a strategy for dam releases, including managing tributary inputs with BHBFs, without sediment augmentation) that will restore and maintain sandbar habitats over decadal time scales?
- **SSQ RIN 4.** What are the effects of ramping rates on sediment transport and sandbar stability?
- **SSQ RIN 5.** What is the rate of change in eddy storage (erosion) during time intervals between BHBFs?

Also identified as part of the GCDAMP Strategic Plan are several CMINs, which are briefly summarized in table 2.

### **Monitoring and Research Activities**

Three monitoring and research activities are categorized below: core monitoring, research and development linked to monitoring and modeling, and long-term flow experimentation. In the case of goal 8, monitoring activities for detecting changes in sand storage throughout the river ecosystem were extensively reviewed through the sediment transport modeling review PEP, or SEDS-PEP (final report available at [www.gcmrc.gov](http://www.gcmrc.gov)) process during 1998–2006. The SEDS-PEP review process for sediment monitoring was concluded in August 2006 with a final meeting and report to the GCMRC. Recommendations for future monitoring will be integrated into the science planning process during 2007, as planning for the FY2008–09 biennial work plan occurs. As a result of the timing associated with this ongoing process, only general elements of long-term sediment monitoring are discussed in this section of the MRP.

**Table 2.** Overview of core-monitoring information needs related to GCDAMP goal 8.

| Environment                  | Discharge range (cfs) | Goal 8 core-monitoring information need(s)   |   |
|------------------------------|-----------------------|--|---|
| Tributaries                  | N/A                   | Monthly sand and silt/clay input volumes and grain-size characteristics from the Paria and Little Colorado Rivers and other major tributaries like Kanab and Havasu creeks, and “lesser” tributaries |   |
| Main channel                 | <5,000                | Annual or biennial fine-sediment volume and grain-size changes by reach  | Monthly sand and silt/clay loads and grain-size characteristics at Lees Ferry, Lower Marble Canyon, Grand Canyon, and Diamond Creek |
| Channel margins (not eddies) | 5,000–25,000          | Annual or biennial sandbar area, volume and grain-size changes by reach  |   |
| Eddies                       | <5,000                | Annual or biennial sandbar area, volume and grain-size changes by reach  |   |
|                              | 5,000–25,000          | Annual or “event” sandbar area, volume and grain-size changes by reach   |   |
|                              | >25,000               | Annual or biennial sandbar area, volume and grain-size changes by reach  |   |
| Throughout the CR ecosystem  | N/A                   | Annual event to decadal scale changes in coarse sediment (>2 mm) abundance and distribution  |   |

### Core-Monitoring Activities

Core-monitoring activities will focus on

- Monitoring and reporting annual or biennial field measurements (site-specific conventional surveys) on the status of sandbar area, volumes, and grain-size characteristics at a selected subsample of sandbars within specified geomorphic reaches
- Monitoring and reporting remotely sensed measurements of sandbar areas systemwide, as derived from multispectral, orthorectified, digital imagery flown once every 4 years (this monitoring is proposed to be preempted during years with BHBF tests)
- Monitoring and reporting changes in the distribution and abundance of shoreline types pertaining to terrestrial and aquatic habitats of interest to managers, such as backwaters,

camping areas, cultural preservation sites using data derived from multispectral, orthorectified, digital imagery flown once every 4 years

- Monitoring and reporting changes in the geomorphic impacts along the CRE that result from tributary debris flows and stream floods, as needed

#### Monitoring Changes in Sediment Storage

##### *External Peer Review of Sediment Protocols in 2006–07*

The external review of sediment protocols to take place during 2006–07 will be followed by planning for sandbar monitoring for implementation in 2008–11 and beyond.

Recommendations from external peer reviewers on options for monitoring of sediment storage throughout the ecosystem will be incorporated into a GCMRC-led core-monitoring workshop with the TWG during 2007. The purpose of the 2007 workshop is to ensure that stakeholder information needs related to sediment resources are considered during planning for future monitoring. The GCDAMP's approved core-monitoring information needs for sediment are summarized in table 2.

Of these information needs for sediment, the GCDAMP stakeholders recently identified monitoring focusing on measurements and modeling estimates of sediment inputs from major tributaries as the most important monitoring activity (see goal 7, this report). The measurement of changes in the amount of fine sediment below the 5,000-cfs stage was listed as the next most important activity. The measurement of changes in high-elevation sandbars along the main channel of the ecosystem was the third most important activity. Because retention of tributary sand inputs has been identified by scientists and managers as a precursor for experimental BHBFs intended to restore and maintain sandbars, sand export from the ecosystem is also a monitoring priority in research to evaluate sediment triggers for future high-flow tests.

Owing to the fact that fine-sediment deposits (beaches within eddies) are closely related to the distribution of coarse-grained sediment deposits (tributary debris fans), core monitoring for changes in gravel deposits is also needed at decade-scale periods to fully evaluate changes in sand beaches, whitewater rapids, and related geomorphic settings and habitats. On average, sand storage will be monitored every 2 years; however, more frequent measurements will be taken in conjunction with experimental flows such as BHBFs.

#### Monitoring Changes in Coarse-Grained Sediments and Impacts from Tributary Debris Flows

Core-monitoring activities related to coarse sediment in the ecosystem are to be determined during FY2007, following external peer review and a report on recommendations from the SEDS-PEP panel meeting (August 2006). Future core-monitoring efforts for both fine- and coarse-grained sediment deposits will be planned according to the core information needs of managers (table 2), results from recent research and development (2000–06 study results), external peer review, and planning with the TWG.

Over 700 tributaries have the potential to contribute coarse-grained sediment to the CRE. The addition of coarse sediment is known to alter beaches and debris fans and can change the way that finer sediment is stored throughout the main channel. Such changes occur as a result of aggregation of main channel rapids, upper pools, and runs above rapids and through deposition of new gravel on existing debris fans and eddies. These geomorphic changes influence the

ecosystem's flow dynamics in and between rapids and effectively increase the abundance of gravel substrates spatially. Monitoring of changes resulting from continuing tributary inputs of gravel will be conducted on a systemwide basis through the use of remotely sensed imagery once during 2007–11, using imagery obtained in 2005 and 2009. Additional field activities may be scheduled to perform ground truthing in support of change detection. In the event of larger tributary debris flows that significantly alter the navigational characteristics of the main channel, additional field activities may be needed on a contingency basis. Monitoring data from this project will be reported to managers at biennial science symposia and TWG meetings (on a period basis) and will be available for integration into other resource area efforts, such as food web, cultural/recreational, and fisheries projects.

## Research and Development Activities

### Development of Core-Monitoring Protocols for Sediment

From 2000 through 2006, research and development projects were proposed, funded competitively through solicitations, and completed by a consortium of sediment scientists from the USGS, NAU, and Utah State University (USU). The results of these long-term studies were evaluated in summer 2006 by an expert panel of sediment scientists, who were charged with developing science-based recommendations for protocols to use in core monitoring of sandbar changes throughout the CRE. Additionally, the review panel critically evaluated the results of a major-sediment-modeling initiative programmed by the GCMRC between 2001 and 2006. While the sediment PEP's final report includes recommendations for additional research studies and evaluations, the main goal of the GCMRC is to incorporate the panel's review recommendations into a core-monitoring plan for goal 8 (sediment) information needs in FY2008 and beyond. The proposed schedule for core monitoring is likely to be tied to a biennial strategy of field measurements, as well as change-detection mapping and evaluation tied to airborne remote-sensing overflights (digital imagery) collected once every 4 years. The next such mission is proposed in FY2009.

### Strategy for Ongoing Development of Sediment-Transport Models

The October 2006 SEDS-PEP final report related to proposed FY2007 modeling activities indicates the need for additional testing and review of the sand-transport-modeling project. This research project (2002–06), funded through competitive solicitation in FY2001, was focused on simulating the short-term (i.e., weeks to months) fate of tributary inputs using a pseudo-one-dimensional model, as well as modeling the effects of a single BHBF on eddy storage. Comments from the SEDS-PEP indicated substantial concern regarding the adequacy of the existing sediment-transport models for the CRE. Therefore, the original FY2007 modeling work plan (referred to in goal 7, this report) has undergone modification to include further testing of the models by their developers, as well as additional peer review that will be conducted in a focused workshop to be held in spring 2007. A second important recommendation from the PEP related to sand-transport modeling was the need to develop a model for simulating the long-term fate (i.e., years to decades) of sandbar deposits. A long-term model would be an invaluable tool for evaluating various flow-only alternatives (presumably centered around repeated use of BHBFs) for restoring sandbars over decadal time scales (i.e., answering the strategic sediment

question above). Thus, the additional sand-transport model review will occur in FY2007 in combination with a workshop to formulate a strategy for development of this long-term model, which could be implemented in FY2008–09.

## Long-Term Experimental Activities

Generally, the experimental science support objective for goal 8 is tied to evaluation of flow-only options for sandbar restoration and maintenance through use of BHBFs. For this reason, in support of the evaluation of experimental flows from GCD, GCMRC program staff will collect, as need arises, additional sand storage data throughout the main channel of the CRE.

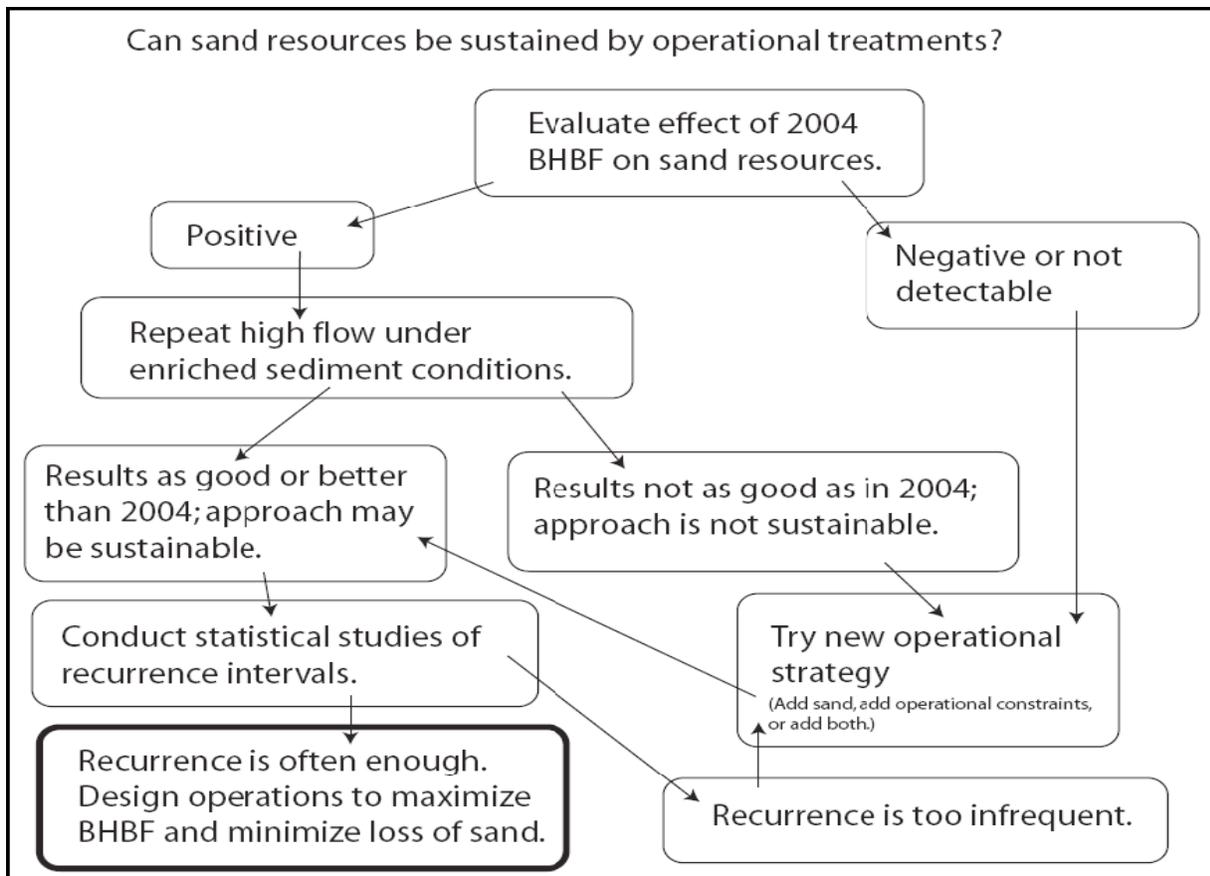

Two specific types of experimental sediment activities that are anticipated during the FY2008–11 period of monitoring and research are described below.

### Experimentally Replicate the 2004 Beach/Habitat-Building Flows Test

Sediment research results from the 2004 BHBF test suggested that short-duration, 41,000–45,000-cfs dam releases in the same season or year that significant sand is delivered to the Colorado River by larger tributaries can result in a net positive change in sandbar resources. Following this result, sediment scientists recommended that the sediment-enriched test be repeated during the winter or spring months to determine whether repeated releases following sediment inputs might be a sustainable means of restoration and maintenance of sandbars and related ecosystem habitats. The logic associated with such an experimental strategy for sandbar restoration is shown in figure 3.

In the event that results from a repeat of the sediment test conducted in 2004 (similar with respect to sand enrichment regardless of seasonal timing) are not net positive, then future tests might need to occur when more highly constrained dam releases allow downstream tributary sand inputs to accumulate over time or when sand can be imported from upstream sources (or perhaps some combination of both).

The strategy of attempting to replicate the net positive sand mass balance documented as the result of the 2004 BHBF test is intended to answer the primary strategic science question for sediment (SSQ 4.1) listed above. If a future BHBF test suggests that the flow-only operational strategy for sandbar restoration is sustainable through repeated implementation following tributary sand inputs, then additional monitoring and research (perhaps combined with flow and sediment modeling) might determine the optimal recurrence interval for BHBFs that is required to achieve the desired sandbar resources throughout the ecosystem.

**Figure 3.** Flow chart showing the proposed experimental strategy for evaluating a flow-only operational strategy. The experiment will evaluate if restoration and maintenance of sandbars below Glen Canyon Dam can be successful using repeated beach/habitat-building flows during years when tributaries produce average to above-average sand inputs to the Colorado River ecosystem.

#### Experimentally Evaluate Alternative Ramping Rates

The stability of sandbars and their fate following BHBFs under patterns of diurnal fluctuating releases is another important topic of concern for the GCDAMP. One of the critical elements of daily fluctuating operations linked with sandbar stability is the hourly rates at which flows are increased and decreased. This operational parameter relates to sandbar stability, particularly with regard to the downramp rate of dam releases that affect the rate at which perched water within sandbars is able to drain from beach sands as the river stage drops toward the daily low flow. Alternative ramping rates, particularly increased downramp rates, are therefore identified as a priority for further experimental flow research to determine if downramping at more than the currently allowed rate of 1,500 cfs/h significantly increases sandbar erosion rates between episodes of beach building and sandbar restoration.

Data relating to SSQ 4 -1 will be collected through monitoring measurements made before and after future BHBFs, using methods developed for sandbar monitoring during the 2000–05 era of research and development. Sandbar measurements will focus on areas identified

in recent synthesis research reports as representative for eddy and sandbar responses within Glen, Marble, and Grand Canyons. Resolving the answer to SSQ 4-1 assumes that data from at least one more sand-enriched BHBF test will be obtained in the research period of 2007–11 (to be compared with data from the 2004 BHBF test).

Data relating to alternative ramping rates (SSQ RIN 4) could be collected through experimental field measurements, modeling, and laboratory studies of alternative fluctuating flows during 2008–11. This research represents a return to the type of research and development that was conducted during the 1990–94 EIS era, using methods for sandbar monitoring developed during 2000–05. New methods will also be used to refine information on how alternative ramping rates and daily stage ranges (relative to the ROD) influence sandbar stability and related habitats below the dam. Ongoing monitoring data on suspended-sediment transport will also be evaluated to determine how alternative fluctuating flow operations influence downstream sand transport (export).

## **Integration**

Beginning in 2003, monthly integrated science meetings have been convened by the GCMRC to identify methods for linking past and present monitoring and research activities to one another. At these meetings, staff and cooperating scientists discuss SSQs that have been identified by stakeholders and evaluate the monitoring and research progress being made by individual projects in the program. Future integration efforts are generally identified and considered during the annual science planning process, which is conducted jointly between GCMRC Program Managers and the TWG to develop budgets and work plans.

To better support integrated science activities, the GCMRC has also worked within and between individual projects to ensure that databases are documented in terms of metadata as they enter the GCMRC Oracle database. This initiative is an ongoing task of the GCMRC's DASA Program and is intended to allow for integrated analyses of spatial data as integrated studies are identified.

Sand storage studies will continue to be integrated into monitoring and research on recreation camping sites, terrestrial vegetation, archaeological sites, and nearshore habitats and substrate distributions related to fish and food web dynamics in the aquatic ecosystem. Most importantly, the changes in sand storage that are measured through monitoring and mapping will be used to verify results of the fine-sediment mass flux element of the downstream IQW project, as well as to verify sand-transport- and sandbar-modeling results.

Observations of changes in the distribution, abundance, and morphology of gravel that are derived from monitoring of coarse-grained deposits will be related to recreational whitewater boating (navigation), terrestrial and aquatic substrate, campsite areas, nearshore habitats (backwaters), and the abundance and distribution of sand storage throughout the ecosystem (changes in eddy storage). An example of an integrated project related to sediment resources is the analysis of mapping shoreline habitat changes project (DASA 12.D6.07). During FY2007, the GCMRC staff and its science cooperators will undertake efforts at mapping changes in the distribution and abundance of sandbars and related nearshore habitats throughout the CRE. This effort will be undertaken as an experimental support activity associated with the collection of digital remotely sensed imagery from May 2005 (systemwide data were also collected in 2002

and 2004) and is directly related to conservation measures identified with the November 2004 BHBF test.

## **GCDAMP Goal 9: Maintain or improve the quality of recreational experiences for users of the Colorado River ecosystem, within the framework of the GCDAMP ecosystems goals**

### **Strategic Science Questions and Information Needs**

Maintaining or improving the quality of the recreational experience is a multifaceted and complex goal. For example, dam operations affect a myriad of physical and biological attributes that have direct or indirect effects on river-based recreation, and a specific flow regime may have both positive and negative effects on different attributes of the overall recreation experience. As a result, the MRP seeks to address discrete scientific questions, information needs, and objectives required to achieve goal 9.

In 2004, the AMWG identified several priority questions. Priority 3 relates directly to goal 9: What is the best flow regime?

In addition, a number of SSQs related to the effects of flows on recreation emerged from the knowledge assessment workshop conducted in July 2005. These SSQs are primarily targeted at improving our understanding of how flows affect biophysical conditions and social attributes that are important to the quality of recreation experiences in the CRE. The most critical SSQs that emerged as the focus of monitoring and research activities for goal 9 are the following:

1. **SSQ 3-6.** What GCD operations (ramping rates, daily flow range, etc.) maximize trout fishing opportunities and catchability?
2. **SSQ 3-7.** How do dam controlled flows affect visitors' recreational experiences, and what is/are the optimal flows for maintaining a high quality recreational experience in the CRE?
3. **SSQ 3-8.** What are the drivers for recreational experiences in the CRE, and how important are flows relative to other drivers in shaping recreational experience outcomes?
4. **SSQ 3-9.** How do varying flows positively or negatively affect campsite attributes that are important to visitor experience?
5. **SSQ 3-10.** How can safety and navigability be reliably measured relative to flows?
6. **SSQ 3-11.** How do varying flows positively or negatively affect visitor safety, health, and navigability of the rapids?
7. **SSQ 3-12.** How do varying flows regimes positively or negatively affect group encounter rates, campsite competition, and other social parameters that are known to be important variables of visitor experience?

The GCDAMP identified several core-monitoring information needs under each of the five recreation management objectives. The SPG subsequently refined and prioritized the CMINs to define the most important monitoring needs of each goal in order to allocate future funding. The latter process resulted in the following ranking of CMINs for recreation:

1. **CMIN 9.3.1.** Determine and track the size, quality, and distribution of camping beaches by reach and stage level in Glen and Grand Canyons.

2. **CMIN 9.1.1.** Determine and track the changes attributable to dam operations in recreational quality, opportunities and use, impacts, serious incidents, and perceptions of users, including the level of satisfaction, in the CRE.
3. **CMIN 9.5.1.** Determine and track the frequency and scheduling of research and monitoring activity in Glen and Grand Canyons.
4. **CMIN 9.1.2.** Determine and track the frequency and scheduling of river-related use patterns.
5. **CMIN 9.2.2.** Determine and track accident rates for visitors participating in river-related activities including causes and location (i.e., on-river or off-river), equipment type, operator experience, and other factors of these accidents in the CRE.

Note: In June 2005, a PEP reviewed the entire GCDAMP recreation program and produced a final report (Loomis and others, 2005), which included numerous recommendations for improving GCMRC's recreation monitoring and research program. The recreation PEP recognized that most of the recommended monitoring and research programs had the potential to benefit both the GCDAMP and the NPS CRMP. In addition to the SSQs, the recommendations provided in the PEP report form the foundation for the FY2007–11 recreation program described below.

## **Monitoring and Research Activities**

Monitoring and research activities related to recreation for FY2007–11 encompass all three elements of the MRP: core monitoring, research and development, and experimental activities.

### **Core-Monitoring Activities**

#### **Status and Trends in Campsite Area**

A key concern of recreational rafters in Grand Canyon is the diminishing number and size of campsites along the Colorado River. In FY2007–11, the GCMRC will continue to monitor changes in campable area at the NAU sandbar study sites, while concurrently exploring alternative methods to evaluate changes throughout the CRE.

#### **FY2007–11. Sandbar and Campable Area Monitoring (Project REC.9.R1.07)**

In FY2007–11, the GCMRC will monitor campable area at the NAU sandbar study sites using conventional survey methods as in the past (Kaplinski and others, 2005), but with more emphasis on differentiating optimal campable area (level and flat sandy areas) from suboptimal campable area (sloping, lightly vegetated, and/or rockier terrain). A major thrust of the FY2007–11 monitoring program will be to more closely integrate the campable area monitoring work with that of the NAU sandbar monitoring program so that the latter program can inform the former on the effects of changing sandbar area and morphology on campable area.

Concurrently, in FY2007, the GCMRC will explore options for using remote-sensing data to evaluate changes in campable area through focused research and development (see Project REC 9.R2.07 and Project REC 9.2.R3.07 below).

## Status and Trends in Recreational Angling

A key interest of recreational anglers in lower Glen Canyon is the quality of the RBT fishery (specifically size, number, and health of fish), which is directly related to the available food supply. In FY2007–11, the condition of the Lees Ferry trout fishery will be monitored through routine stock assessment procedures conducted by AZGFD (see goal 4, this report). In addition, the GCMRC proposes to work with AZGFD biologists to upgrade the quality and consistency of angler satisfaction data being collected through intermittent AZGFD-sponsored creel surveys. In addition to trout condition and numbers, anglers have previously expressed concern about fishing conditions (“fishability”) and boating access upstream from Lees Ferry, and they also have concerns about safety issues (primarily for waders and independent shoreline fishermen) because of fluctuating flows. All of these issues have direct relevance to the goal of maintaining a high-quality recreation experience. The role of fluctuating flows in affecting fishability and boater safety will be evaluated as part of the long-term experiment (see discussion under ramping rate experiments), while a focused research effort will be conducted in FY2008–09 to improve our understanding of how flows affect other recreational attributes (see Project 9.R5.08 below).

## Research and Development Activities

The 2005 recreation PEP recommended that the GCMRC initiate several foundational research studies to provide a baseline of information against which future experiments and management actions can be evaluated. Furthermore, they recommended that the GCMRC invest in studies to provide data that could be used to better predict the effects of experiments and management flows on recreation in lieu of investing in long-term visitor satisfaction monitoring programs. The following research programs will be implemented in FY2007–11 in response to the 2005 PEP recommendations.

### FY2007–08. Compile Campsite Inventory and Geographic Information Systems Atlas (Project REC 9.R3.07)

The last comprehensive campsite inventory was completed more than 20 years ago after the 1983 uncontrolled release from GCD. Many of the camps identified during that survey have fallen into disuse or disappeared entirely because of sandbar changes and vegetation encroachment, while some new ones have emerged. A new inventory is needed to evaluate changes in the CRE during the past two decades and to provide an up-to-date baseline for designing future studies. In FY2007–08, an up-to-date inventory and Geographic Information Systems (GIS) atlas of all previously and currently available campsites in the CRE will be compiled. The atlas will include information on campsite attributes that are known to be important to visitors (e.g., physical size, estimated size of group that can be reasonably accommodated, frequency of use, amount of open sand versus vegetation, availability of shade, mooring attributes, etc.). This baseline inventory will define the population of campsites from which samples can be drawn to characterize systemwide changes, and it will serve as the basis for evaluating recreation impacts on other CRE resources of concern such as archaeological sites.

FY2007. Evaluate Campable Area Monitoring Results Using Measured Field Data vs. Remotely Sensed Data (Project REC 9.R2.07)

A comparison of campable area monitoring results derived through field measurements and GIS-based analysis of remotely sensed imagery and topography will be completed in FY2007. A pilot effort conducted in FY2005 demonstrated that estimates derived from remotely sensed data consistently overestimated campable area, compared with measurements derived from field surveys; therefore, one desired outcome of the proposed study will be the development of an algorithm to allow comparisons of previously collected campable area data (derived from field surveys) with future data derived from remotely sensed imagery. Depending on the study results, it may be possible to transition the campable area monitoring program to one based largely, or exclusively, on remotely sensed imagery.

FY2007. Compile and Analyze Existing Safety Data (Project REC 9.R4.07)

Using graduate student labor, existing safety data maintained in various NPS databases and in published and unpublished reports will be compiled and evaluated as a prelude to conducting safety and navigability evaluations under experimental flows. This project is targeted for implementation in FY2007 contingent on the availability of funding. If funding is not available in FY2007, the project will be deferred to FY2008.

FY2008–09. Evaluate the Relative Importance of and Tradeoffs to Recreation-Related Attributes Affected by Flows on Recreation Experience (Project: REC 9.R5.08)

The quality of a recreation experience is determined by multiple interacting physical, biological, and social factors, many of which are affected by flows (e.g., the size, quality, and distribution of campsites; the size, navigability, and “thrill-factor” of the rapids; the rate of boat movement downriver with consequent implications for social encounters and crowding; and the size, abundance, and condition of RBT). Flows affect these recreational attributes in varying and sometimes conflicting ways. The purpose of this study is to determine the relative importance of the recreation-related physical, biological, and social attributes and conditions that are affected by flows, and to analyze the tradeoffs to recreational experience quality that are created by implementing various flow regimes.

FY2009. 1973 Weeden Survey Revisited

The 1973 Weeden survey was the first attempt to comprehensively inventory and document campsites in the CRE. This effort produced hundreds of photographs and aerial imagery maps of CRE campsites. The NPS is currently working on relocating the photo points used to obtain the images. In FY2007–08, using CRMP funding and both volunteer and professional photographers, the NPS will duplicate the aerial imagery and related campsite data from the 1973 Weeden survey. In FY2009, these data will be integrated into the campsite atlas, and a formal analysis of differences between the photographic images from the Weeden survey and identical images collected in 2007–8 will be undertaken to provide a diachronic perspective on campsites change in the CRE during the past 35+ years.

#### FY2009. Quantify Vegetation Encroachment at Campsites

Vegetation encroachment rates and their relative significance in diminishing campable area will be evaluated by using remotely sensed imagery to compare vegetated areas from a stratified sample of heavily used and infrequently used camps and analyzing these data in a GIS environment.

#### FY2010–11. Update Regional Recreation Economic Studies

By FY2010, existing economic baseline studies will be 20 to 25 years old (!), so in FY2010–11, economic valuation studies for CRE-based recreation will be repeated.

### Long-Term Experimental Activities

Several studies will be initiated in conjunction with the experimental flows of FY2008–11 to evaluate the effects of various experimental flows on recreation. These studies will evaluate the effects of BHBF and ramping rate experiments on beach morphology, size, and distribution (e.g., campable area), as well as post-BHBF effects on the Lees Ferry trout fishery and angling experience. In addition, GCMRC will partner with NPS to evaluate effects of high, low, steady, and fluctuating flows on human health and safety.

#### Evaluate Effects of Ramping Rates and BHBFs on Campsites

Changes in campable area within the CRE are the result of a variety of flow-related factors, including changes in sediment deposits, modification of sandbar topography, and vegetation encroachment. This project will focus on evaluating the roles of different ramping rates and effects of BHBFs on these three critical attributes.

#### Evaluate Effects of BHBFs, Low Steady Flows, and Fluctuating Flows on Navigability and Safety

Safety issues associated with high and low flows and varying ramping rates were a primary concern of the public during the scoping phase of the GCD EIS process. This project will build upon previous studies undertaken during past experimental flows to assess how changes in flow volume and ramping rates affect the numbers and types of river-based incidents that could affect the safety of recreational anglers and whitewater boaters in the CRE. The proposed safety data compilation study (Project REC.9.R4.07) will provide a foundation for this experimental study.

#### Evaluate Effects of Steady Flows vs. Fluctuating Flows on Visitor Health

Issues associated with human health were identified by river guides in relation to the low summer steady flows (LSSF) experiment of 2000, when many boating parties in Grand Canyon were affected by a waterborne virus. Although possibly a coincidence, the Norwalk viral outbreak of summer 2000 raised the possibility that certain flow regimes might be more conducive to spreading human pathogens than others. This project will evaluate human health risks associated with different experimental flows. Specifically, the study will attempt to determine if steady flows or highly fluctuating flows have a measurable effect on sanitary

conditions at heavily used camping beaches. This project will be implemented through a cooperative partnership with the NPS.

## **Integration**

### **Physical Science Program**

Changes in campable area are largely, but not exclusively, caused by changes in sandbar area and volume. Other factors that may be contributing to campsite area decline in the CRE include changes in bar morphology (e.g., steeping of slopes under certain flow regimes). Evaluating the effect of sandbar morphology on campable area requires comparisons of topographic data derived from the sand storage monitoring program against prior campable area survey results. This program underwent a PEP review in FY2006 in part to define core-monitoring protocols for tracking sediment storage in the CRE. Although the protocols for sand storage monitoring have not yet been defined, campable area monitoring will continue to a large degree to rely on and be integrated with data derived from the Physical Science and Modeling Program.

In addition, flow-stage modeling based on the improved sediment transport and river simulation (STARS) model will be useful for defining stage relations at camps for which survey data are not currently available. The analysis and storage of campsite data and the creation and maintenance of the GIS atlas will require direct involvement from GCMRC's DASA Program.

### **Biological Sciences**

Monitoring of trout condition is a critical proxy measurement for angler satisfaction in lower Glen Canyon. GCMRC and AZGFD will work together to define additional angler satisfaction measurements that can be collected through periodic AZGFD creel surveys.

Although sand supply is a critical factor affecting campable area in the CRE, another significant process that may be contributing to campsite loss is vegetation encroachment. Evaluating the role of vegetation encroachment on campable area will require using remotely sensed vegetation data collected during the 2000, 2002, 2005, and 2009 missions and the results of the ongoing vegetation mapping effort (Project BIO 6.R1.07), in combination with the data developed for the GIS campsite atlas (Project REC 9.R3.07.)

### **NPS Colorado River Management Plan**

As discussed in the PEP review of the GCDAMP recreation program, there is considerable overlap in information needs for the CRMP and the GCDAMP. However, while closely intertwined, the interests and emphases of these two programs are not identical: the CRMP is primarily focused on evaluating the effects of NPS visitor management decisions on river-based visitor experience qualities and associated physical and biological resource values, while the GCDAMP is concerned primarily with monitoring and researching effects of dam operations on CRE resources, including the visitor-use values associated with those resources. The GCDAMP recreation program has historically focused on the effects of dam operations (flows) on physical and biological attributes important to recreation (e.g., camping beaches, trout), although multiple GCDAMP reviews have identified the need for more emphasis to be placed on the social/experiential and economic effects of dam-controlled flows. Also, the

geographic scope of the GCDAMP is considerably more restricted than that of the CRMP. The CRMP addresses issues associated with visitor use of side canyons and other attraction sites accessed from the river but located outside the mainstem river corridor, whereas the focus of the GCDAMP is on the CRE.

The NPS has been allotted \$500,000 per year for the next 5 years to design and implement monitoring and research programs relevant to the information needs of the CRMP.

To the extent that these programs overlap with those of the GCDAMP, it will be beneficial for the GCMRC and the NPS to develop coordinated, integrated, and jointly funded projects to satisfy multiple needs simultaneously. However, since some CRMP-driven needs for information lie outside the scope of the GCDAMP, not all CRMP funding will apply to resources of mutual concern. Projects that are likely to be jointly funded and comanaged in the next 5 years include the campsite inventory and GIS atlas, the safety data compilation, evaluation of ramping rates and steady flows on visitor health, and duplication of the Weeden survey photographs.

## **GCDAMP Goal 10: Maintain power production capacity and energy generation, and increase where feasible and advisable, within the framework of the Adaptive Management ecosystem goals**

### **Strategic Science Questions and Information Needs**

In August 2004, the AMWG identified the third priority question: “What are the best flows?” This question has obvious implications for hydropower, because “the best flows” are evaluated both from the perspective of optimizing hydropower generation and also in terms of optimizing benefits to other resources, such as endangered fish and sediment. Power-production capacity and the related economic activities are tied to a range of variables. For this reason, the MRP focuses on discrete scientific questions, information needs, and objectives.

The 2005 knowledge assessment workshops identified two key SSQs related to goal 10, which are as follows:

1. **SSQ 3-3.** What are the hydropower replacements costs of the MLFF (annually, since 1996)?
2. **SSQ 3-4.** What are the projected costs associated with the various alternative flow regimes being discussed for future experimental science (as defined in the next phase experimental design)?

The GCDAMP SPG reviewed, revised, and prioritized the CMINs in the GCDAMP Strategic Plan. The SPG redefined the primary core-monitoring information need for goal 10 as follows:

1. **CMIN 10.1.1.** Determine and track the marketable capacity and energy produced through dam operations in relation to the various release scenarios (daily fluctuation limit, upramp and downramp limits, maximum flow limit of 25,000 cfs, minimum flow limit of 5,000 cfs).

### **Monitoring and Research Activities**

#### **Core-Monitoring Activities**

Data on GCD hydropower generation and opportunity costs under MLFF operations have been identified as information needs by the GCDAMP. These parameters are routinely monitored by Reclamation and the Western Area Power Administration (WAPA), but the data are not readily accessible to most GCDAMP stakeholders. To meet the need for core-monitoring information related to power generation and replacement costs, WAPA will provide data on power generation and marketable capacity valuations. These data will be provided to the GCMRC on a daily or monthly basis depending on the parameter. The data will then be made available through the GCMRC Web site.

FY2007–11 (New). Monitor Power Generation and Market Values under Current and Future Dam Operations (Project HYD 10.M1.07)

Reclamation tracks hourly hydropower generation capacity, and WAPA and its customers track power source availability and market changes on an hourly basis in assessing the need, cost, and accessibility for additional power resources to meet contractual obligations or

unanticipated demand. Market pricing, resulting cost of power purchases, and the impact on Basin Fund cash flow are recorded in the WAPA Energy Tracking Database (ISA) and reported monthly. In FY2007, the GCMRC will work with Reclamation and WAPA to serve and archive these existing hydropower and replacement-cost data through the GCMRC Web site in order to address this current program information need shortfall.

### Long-Term Experimental Activities

Experimental flow studies are currently (FY2006) being discussed that would evaluate alternative ramping rates and daily fluctuating ranges. These studies would initially focus on the influence of such alternative operations on downstream sandbar stability and related habitats, and eventually on other related ecosystem processes, but effects on costs to power generation capacity must also be considered.

Economic implications of various flow regimes, in terms of energy generation capacity and power replacement costs, are important variables to consider when selecting future flow regimes, yet with few exceptions (e.g., the LSSF experiment of 2000), independent, peer-reviewed data and analyses on costs and revenues associated with various dam operations have not been readily available for the GCDAMP to factor into their recommendations to the DOI.

In preparation for conducting future experimental flows, an economic analysis of predicted hydropower opportunity costs under various alternative experimental scenarios is being undertaken in FY2006. This study will evaluate the economic implications of various experimental flows being considered by the GCDAMP in terms of energy generation capacity and replacement costs. WAPA and Colorado River Energy Distributors Association (CREDA) are providing input on the models and assumptions used to generate the results and will provide hydropower production cost and power sales data to be factored into the analyses.

#### FY2010–11. Evaluate Economic Implications of Experimental Flows

Once the experiment is initiated, the GCMRC will track costs associated with the experiment using the monitoring program described above. The evaluation of economic implications will focus primarily on hydropower replacement costs and associated impacts to the Basin Fund. In FY2010–11, the GCMRC will conduct an independent analysis to determine whether the predictions were accurate or not, and to determine where and why they may have deviated from projected outcomes.

# **GCDAMP Goal 11: Preserve, protect, manage, and treat cultural resources for the inspiration and benefit of past, present, and future generations**

## **Strategic Science Questions and Information Needs**

In August 2004, the AMWG identified the following questions as the second highest priority of the GCDAMP: “Which cultural resources, including TCPs, are within the Area of Potential Effect from dam operations, which should we treat, and how do we best protect them? What are the status and trends of cultural resources and what are the agents of deterioration?” Since that time, Reclamation and the NPS have agreed to develop a treatment plan for 161 archaeological sites of the 323 sites potentially affected by dam operations in the CRE. The sites subject to treatment have been determined by NPS to be actively deteriorating through a variety of agents. With immediate treatment needs now being addressed by Reclamation and NPS, GCMRC monitoring and research activities will focus on assessing the overall status and trends of cultural resources in the CRE, the relative contributions of the agents of deterioration in affecting cultural resources, and the long-term effectiveness of the treatment measures.

To focus monitoring and research activities for cultural resources even more, the MRP is placing its attention on five key SSQs, which are as follows:

1. **SSQ 2-1.** Do dam controlled flows increase or decrease rates of erosion at arch sites and TCP sites, and if so, how?
2. **SSQ 2-2.** How do flows impact old high-water zone (OHWZ) terraces in the CRE, and what kinds of important information about the historical ecology and human history of the CRE are being lost due to ongoing erosion of the Holocene sedimentary deposits?
3. **SSQ 2-3.** If flows contribute to arch site/TCP erosion, what are the optimal flows for minimizing impacts to these cultural resources?
4. **SSQ 2-4.** How effective are various treatments (e.g., check dams, vegetation management, etc.) in slowing rates of erosion at archaeological sites over the long term?
5. **SSQ 2-7.** Are dam controlled flows affecting TCPs and other tribally-valued resources in the CRE, and if so, in what respects are they being affected, and are those effects considered positive or negative by the tribes who value these resources?

The GCDAMP also identified several CMINs under goal 11. The GCDAMP SPG subsequently refined and prioritized the CMINs for cultural resources to define the most important monitoring needs under each GCDAMP goal for the allocation of funding. The latter process resulted in the following ranking of CMINS for cultural resources:

1. **CMIN 11.1.1 (SPG revised).** Determine the condition and integrity of prehistoric and historic sites in the CRE through tracking rates of erosion, visitor impacts, and other relevant variables. Determine the condition and integrity of TCPs in the CRE.
2. **CMIN 11.2.1 (SPG revised).** Determine the condition of traditionally important resources and locations using tribal perspectives and values.

## Monitoring and Research Activities

### Core-Monitoring Activities

Past research indicates that dam-controlled flows influence archaeological site condition in a variety of ways. Several hypotheses have been advanced to account for the role of dam operations in archaeological site degradation, but these hypotheses require further research, testing, and refinement. Understanding if and how cultural site condition is affected by dam-controlled flows is important to achieving the stated goals of the GCDAMP and Grand Canyon Protection Act. Because the condition of archaeological sites and other place-based cultural resources is inevitably a product of multiple interacting processes, determining the agents of degradation requires improving our understanding of the full suite of agents affecting cultural resource condition in the CRE (e.g., climate and weather events, human behavior, geomorphic and biotic processes), in addition to conducting research on direct, indirect, and interactive effects of flow regimes. To partially address this need, in FY2006 the GCMRC initiated a multiyear, multifaceted archaeological site-monitoring research and development project to continue during the first years of this MRP. This work is being supported by the compilation and analysis of existing archaeological site legacy data in FY2006–07.

At a minimum, a better understanding of how dam-controlled flows affect erosion rates at cultural sites is needed. This need can be met through implementing monitoring protocols that measure physical change at repetitive intervals and through integrating relevant data from other program areas, such as the physical sciences (e.g., flow-stage modeling, sandbar monitoring) and biological sciences (e.g., terrestrial vegetation monitoring) programs.

To date, very little research has been focused on evaluating how dam operations affect TCPs or other cultural resources besides archaeological sites. In addition to site-specific cultural resources, the Native American tribes who participate in the GCDAMP are concerned about how dam operations may affect traditionally valued terrestrial plants and animals in the CRE. Like the place-based cultural resources, culturally important biological resources are affected by dam-controlled flows both directly and indirectly. Direct effects include periodic inundation and flow-induced scouring and disturbance that prune older plants, induce new growth, open up areas for colonization, impact the characteristics of habitats used by various fauna, and redistribute seeds and nutrients. Direct effects also include consequences related to the timing and frequency of inundation and flow-induced disturbance events. Indirect effects include changes to the sediment substrate from flows, changes to the water table and consequent effects to OHWZ vegetation (e.g., mesquite), and long-term changes in species composition and abundance because of the timing, frequency, and discharge level of dam-controlled flows. Presumably, monitoring and evaluating the effects of flows on culturally significant plants and animals can be most effectively achieved by integrating cultural resource monitoring with physical and biological elements of the science program. In FY2006, the tribes are being funded to synthesize their existing monitoring data and define approaches to monitor culturally important resources in the CRE. In FY2007 or FY2008, the tribes will implement their proposed monitoring programs on a pilot basis (Project CUL 11.R2.07). The results of these and other pilot cultural resource monitoring projects will subsequently be evaluated by a cultural resource PEP in FY2010.

As noted above, core-monitoring programs are currently under development (see discussion under research and development activities section below). The plan calls for

implementation of revised core-monitoring protocols for cultural resources for a 3-year pilot program in FY2008–10, followed by a cultural PEP in FY2010.

#### FY2010 (New). Cultural Protocol Evaluation Panel Review

Following completion of research and development for core monitoring and effects of monitoring and completion of a 3-year pilot monitoring program, a followup PEP review of the cultural program will be conducted to evaluate changes made since the 2000 cultural PEP and evaluate the results of research and development in FY2006–10. Based on the findings of the second PEP, or Cultural PEP II, a refined core-monitoring program will be implemented beginning in FY2011.

### Research and Development Activities

In FY2007, the GCMRC will continue several research and development activities initiated in FY2006 to evaluate the most appropriate core-monitoring indicators and protocols for tracking archaeological site condition and the effectiveness of erosion-control treatments through time. Since erosion of archaeological sites is tied directly and indirectly to dam presence and dam operations, considerable effort will be devoted to refining methods for measuring and tracking erosion. However, erosion is only one of several factors affecting resource conditions, so the evaluation of other indicators, such as human disturbance indicators and weather parameters, will also be pursued.

#### FY2006–07. Research and Development toward Core Monitoring (Project CUL.11.R1.07)

The project involves the following three tasks (for more detail, see project description in the FY2007 annual work plan):

1. **Task 1: Assessment of archaeological sites for future monitoring.** Continue geomorphic and archaeological integrity assessments initiated in FY2006 at a subset of archaeological sites in the CRE to define the most appropriate protocols for future monitoring
2. **Task 2: Continue evaluations of existing legacy monitoring data.** The emphasis will be on evaluating the accuracy, consistency, redundancy, and statistical value of existing monitoring data. In FY2007, we will also focus on defining appropriate applications for the existing data (e.g., attempt to utilize existing monitoring data to detect trends in site condition relative to dam operations) and evaluate the utility and limitations of other legacy data, particularly the extensive photographic record that has been compiled by the NPS over the past 15+ years
3. **Task 3: Continue to evaluate monitoring protocols for quantifying geomorphic change.** This study component will compare and contrast alternative methods for measuring erosion/topographic change at a sample of sites. Specifically, we will evaluate the tradeoffs involved in using conventional survey methods versus ground-based and airborne LiDAR in terms of field and post-field processing time, efficiency, accuracy, precision, costs, equipment limitations, and short- and long-term resource impacts. Additional subtasks that will be included under this protocol evaluation task are

- FY2007–08: Refine protocols for evaluating erosion control effectiveness. In addition to refining protocols for core monitoring, in FY2007–08 the GCMRC proposes to continue evaluating and refining methods for measuring and tracking erosion control effectiveness at a sample of treated sites. This evaluation process will build on a pilot study initiated by USU under the treatment planning effort in FY2006.
- FY2007–08: Test and refine weather-monitoring protocols. This effort will explore options for monitoring weather parameters using various technologies at a sample of intensively monitored archaeological sites distributed throughout the CRE to meet multiple needs for weather monitoring data related specifically to the cultural resource monitoring program.
- FY2007–08: Evaluate terrace changes using remotely sensed imagery in a pilot study. In order to explore the utility of existing remotely sensed imagery for tracking geomorphic change at archaeological sites, the GCMRC will initiate a pilot study in FY2007 to evaluate rates of terrace retreat and arroyo erosion using digitized images of historical aerial imagery. This project hinges on the completion of an ongoing internal FY2006 GCMRC effort to digitize and evaluate the accuracy of historical aerial photographs that are currently stored in hard-copy format at the GCMRC library.
- FY2007–08: Test and refine human impact-monitoring protocols. This effort will explore options for tracking and quantifying impacts of human visitation that result in measurable changes to archaeological site condition. These protocols will be developed in coordination with the NPS Colorado River Management Plan to meet multiple agency needs for human impact data in the CRE.

#### FY2008–10. Pilot Integrated Archaeological Site Monitoring and Tribal Resources Monitoring Projects

As noted above, the results of this initial research and development phase will be incorporated into a pilot version of an integrated cultural resource monitoring project that will be implemented in FY2008 on a trial basis for a 3-year period. The archaeological site monitoring program is being developed by the GCMRC in collaboration with Reclamation, NPS, Native American tribes, and other GCDAMP stakeholders to comply with Sections 106 and 110 of the National Historic Preservation Act (for both Reclamation and NPS) and the mandates of the Grand Canyon Protection Act. In FY2006, the tribes are being funded to refine protocols for monitoring TCPs and other tribally valued resources. The tribal monitoring programs are being developed by the individual tribes who value these resources, but, in the future, the plan is to integrate tribal monitoring efforts with the archaeological site monitoring program where feasible and practical to reduce resource impacts, redundancy, and program costs. The GCMRC will confer with the Cultural Resources ad hoc Group (CRAHG, an ad hoc committee of the GCDAMP TWG) to develop criteria to guide the site selection process for the long-term monitoring program and the specific protocols to be piloted in FY2008–10. The details of the FY2008–10 pilot monitoring programs will be determined upon completion of the initial research and development phase at the end of FY2007 or early in FY2008. This pilot monitoring effort constitutes the second phase of research and development towards core monitoring and will conclude with a PEP review at the end of FY2010.

In FY2009 and beyond, additional research projects will be initiated to refine our understanding of how flows affect cultural resource sites in the CRE. Identified projects include the following:

FY2009–10 (New). Expand Pilot Study to Evaluate Geomorphic Changes in the CRE using Remotely Sensed Imagery

This project will build upon the results of the pilot study initiated in FY2007. It will continue to explore the utility of using digitized historical aerial photographs to track and quantify geomorphic changes because of operations of the dam and interacting physical processes, using methods developed in the FY2007 pilot effort and applying them to other reaches of the CRE with high concentrations of culturally significant resources.

FY2009–10 (New). Geomorphic Model of Archaeological Site Vulnerability

Another important element of the research and development program for cultural resources involves the development of a geomorphic model to quantify future geomorphic change at archaeological sites under various flow and climatic regimes and evaluate future site vulnerability to erosion. This model will be integrated as a submodel of the broader CRE conceptual model that is proposed for development in FY2008–09. Development of the geomorphic model will build on some of the geomorphic and weather data that will be collected through the research and development program for core monitoring and experimental effects monitoring, as well as other data sources (e.g., improved model for stage discharge relations in the CRE).

### Long-Term Experimental Activities

Beginning in FY2008, the following studies will be initiated in conjunction with experimental flows:

FY2008–11. Evaluate Effects of BHBF Sediment Deposition at Archaeological Sites and TCPs.

This focused study will assess the effects of BHBFs at historic properties in terms of subaerial sediment transport rates before and after BHBFs and the effects/rates of retention of flood deposits in arroyo mouths in relation to subsequent erosion at a sample of archaeological sites. This study will partially address SSQ 2-1, SSQ 2-3, and EIN 11.1.1.

FY2008–11. Evaluate Effects of Steady Flows and Fluctuating Flows (ramping rates) on Archaeological Site Sediment Supply

This study will evaluate how critical sandbars that serve or have the potential to serve as key sediment source areas for archaeological sites change under experimental flows and how the sediment transport rates from these sandbars to the archaeological sites are affected by these changes. This study will partially address SSQ 2-1, SSQ 2-3, and EIN 11.1.1.

FY2008–11. Test and Refine the Wiele Model

A model recently developed by Wiele and Torrizo (2005) predicts the response of sandbars at several critical archaeological site areas under varying flow and sediment-supply

conditions. This study will evaluate the accuracy of the model predictions by comparing predicted deposition at these cultural sites against actual measurements of post-flood deposits. This study will partially address SSQ 2-1, SSQ 2-3, and EIN 11.1.1.

## **Integration**

Archaeological site condition is the product of multiple interacting agents, including dam presence, dam operations, human visitation, weather, and various other biological and physical processes. Thus, future monitoring of cultural resource conditions will necessarily rely on data from other GCMRC science programs. It may also require some focused interdisciplinary research for a limited period of time (2–5 years) in order to gather physical and biological data that are relevant to cultural concerns (e.g., tracking weather parameters in proximity to a sample of archaeological sites, measuring erosion rates at intervals that allow for analysis in relation to flow releases from GCD, and relating these data to impacts that are quantified at a sample of cultural sites). Some of these studies are already underway and others are proposed, but increased integration is needed across all program areas.

## **Physical Sciences**

The Physical Science and Modeling Program will continue to track sediment supply and storage in the CRE using methods that will be formalized with respect to the physical sciences following the FY2006 PEP review. The interests of the cultural program remain focused on the creation and retention of sandbar deposits above the 25,000-cfs stage, the potential for backfilling of erosional gullies by BHBFs, the quantification of sediment contributions from higher elevations in the CRE to the systemwide sediment budget, and the potential for redistribution of riverine sediments to higher elevation areas where archaeological sites, terrestrial resources, and TCPs are concentrated. The needs of the cultural program for data related to subaerial sedimentary deposits and processes in the CRE will be incorporated into the future sediment monitoring program.

## **Biological Sciences**

Vegetation growth and cover are important variables affecting erosion rates in the CRE. Repeat mapping capabilities using remotely sensed data that are being developed to quantify vegetation change could also be applied to measuring vegetation change in and around archaeological sites. Once the techniques have been tested and refined, these methods will have utility as monitoring tools for tracking vegetation changes at cultural sites.

The Native American tribes who participate in the GCDAMP are interested both in the implications of vegetation cover for mediating erosion rates at archaeological sites and in monitoring of vegetation and faunal resources of the CRE because of their traditional cultural values. The tribes was to define their needs for biological resources monitoring data in FY2006–07; a PEP of the TEM program was convened in FY2007 to evaluate the tribal monitoring protocols in conjunction with the TEM protocols that were piloted in FY2002–05 by NAU and the University of New Mexico. The PEP was intended to design one or more monitoring approaches to serve the broad spectrum of interests for TEM data, including those of the Native American tribes.

## NPS Colorado River Management Plan

In addition to increasing integration with other GCMRC science programs, close coordination is needed with relevant monitoring and research programs being developed by Grand Canyon National Park (GRCA) under the auspices of CRMP implementation. In FY2006, GRCA is initiating a multiyear research and development effort to improve understanding of the effects of recreational activities on the ecology and condition of natural and cultural resources in the CRE. While not directly focused on improving understanding of dam effects, these research and development programs can improve our understanding by evaluating how visitation could affect rates and types of deterioration at cultural resources. Previous research in GRCA and elsewhere shows that human visitation can adversely impact cryptobiotic crusts and vegetation cover and can lay the groundwork for future gully erosion through compacting soils and creating linear, compacted trails that channel runoff. Proximity to heavily used recreation sites (e.g., campsites) may be a significant variable in determining rates of archaeological site deterioration in the CRE—perhaps equal to or surpassing the effects of dam operations. However, unless and until recreation data can be compiled and analyzed in a systematic fashion, the relationship between recreation sites and archaeological site deterioration remains unknown. As noted previously under goal 9, the GCMRC proposes to closely coordinate future monitoring and research efforts with those of the NPS to reduce redundancy of effort while simultaneously enhancing our understanding of the interactive roles of recreation, dam operations, and weather in affecting cultural resource condition.

## **GCDAMP Goal 12: Maintain a high-quality monitoring, research, and adaptive management program**

Goal 12 includes a variety of activities aimed at maintaining a high-quality science and adaptive management program. These activities transcend GCDAMP goals 1–11 because they are fundamental to addressing priority AMWG questions and related science questions and information needs. The activities fall into the following seven categories:

1. GCMRC staffing
2. Reporting
3. Independent science advice and review
4. Bridging science and management
5. Logistical support
6. DASA
7. Administrative and information technology support

### **GCMRC Staffing**

The objective of this activity is to maintain a staff of quality GCMRC managers and scientists to effectively plan, manage, coordinate, and execute an interdisciplinary science program to meet GCDAMP needs and provide high-quality and timely science support to the GCDAMP work groups.

The GCMRC will maintain a core staff of managers to effectively manage and administer GCMRC projects, supervise staff, oversee contracts and cooperative agreements, track budgets, and create a quality work environment. In addition, GCMRC staff will support the GCDAMP by providing timely scientific reports and information to the GCDAMP and assist the AMWG and TWG to develop and implement effective collaborative management planning and processes. The GCMRC staff was realigned to establish a Deputy Chief position in FY2006 to provide more direct management and supervision of GCMRC activities and to coordinate implementation of the MRP within GCMRC.

The GCMRC will include permanent and temporary science and technical staff to implement or coordinate monitoring and research projects. Contractors and cooperators will conduct a large amount of our field work activities and feed the data back to GCMRC scientists for analysis, synthesis, and publication. GCMRC scientists will be engaged in field monitoring and research when in-house staff members with the appropriate expertise are available and their use is cost effective. The GCMRC will hold its own proposals to the same level of rigorous external peer review as all others.

### **Program Planning and Management (Project ADM 12.A2.07)**

GCMRC's goal is to deliver a comprehensive ecosystem science program over the next 5 years that is effective in responding to management needs articulated through the GCDAMP and by the DOI. Productive, well-qualified personnel are critical to meeting and achieving this goal. To provide strong leadership and a quality science program responsive to the needs of the

GCDAMP, a core program management staff will direct GCMRC operations and oversee the five major program areas: Physical Sciences and Modeling; Biological Science; Cultural and Socioeconomic; Logistics; and DASA. In addition to their program management responsibilities, the Program Managers will also be experts in their respective fields. GCMRC Program Managers and scientific staff will maintain this expertise so they can provide high-quality technical assistance in the form of expert analysis, opinion, and advice to the Chief, TWG, and AMWG, as requested. The Cultural and Sociocultural Program Manager will also function as the Native American Coordinator. The Program Managers will supervise additional technical and support staff, and act as project leads with their cooperators.

## **Reporting**

The objective of this activity is to provide timely reporting of GCMRC science project accomplishments and findings. The GCMRC will work with contractors and cooperators to publish major results and findings in peer-reviewed publications. Final reports and papers will be presented orally to the TWG and AMWG and posted on the GCMRC Web site for ready access by GCDAMP participants and other interested parties. In addition, preliminary findings that have significant management implications will be presented to the TWG or appropriate ad hoc work groups before they are published to facilitate timely use of the new scientific findings in the GCDAMP process. Significant findings will also be published as USGS fact sheets or informational products in accordance with USGS policy. The GCMRC will produce an annual accomplishment report in December of each year that will briefly summarize accomplishments or shortcomings for each project included in the biannual work plan. The annual accomplishment report will also include recommendations for modifications, as needed. In FY2010 and FY2011, the GCMRC will update the KAR and SCORE reports to provide an updated synthesis of science information for use in planning the next phase of science and management activities.

Project Note: Reporting requirements will be subsumed within each project conducted or funded by the GCMRC.

## **Independent Science Advice and Reviews**

The objective of this activity is to ensure that the GCMRC science program is efficient, unbiased, objective, and scientifically sound. To achieve this objective, the SA will provide independent scientific oversight and technical advice. The SA will be used in both a review and advisory capacity during the FY2007–11 period to evaluate the efficacy of the science program. Using the SA in an advisory capacity will be closely monitored to ensure that it does not affect SA objectivity as an external independent review panel.

The SA will be managed and operated in accordance with AMWG approved protocols adopted in October 2000. Eight scientists will serve as SA and an executive secretary will administer, coordinate, and report on their activities. In FY2007, the SA will evaluate the best opportunities for implementing an integrated ecosystem science and modeling approach into the current science program and invoking greater interdisciplinary approaches in FY2008–11 science activities. Specifically, by no later than September 2007, the SA will evaluate opportunities for increased use of integrated ecosystem science paradigms within GCMRC monitoring, research, and experimental activities, including the refinement and use of conceptual and predictive ecosystem models and decision-support tools. The assessment will evaluate improvements in

information required by managers on CRE resources, GCMRC staffing, and costs of implementing new ecosystem strategies. SA recommendations will be reviewed by the GCDAMP and implemented as appropriate in FY2008–11.

In addition to SA reviews, all GCMRC proposals, project-specific work plans, and final reports will be subjected to independent peer review in accordance with the established GCMRC peer-review process.

#### FY2007–11. Independent Reviews (Project ADM 12.A4.07)

To increase the efficiency and quality of the science being developed by the GCMRC and used by the AMWG and the Secretary of the Interior, the GCMRC will maintain the established peer-review process. All unsolicited, solicited, or in-house proposals and all draft reports received by the GCMRC will undergo independent, external peer review. Additionally, the SA will be maintained to provide independent scientific oversight and technical advice to ensure that GCMRC science activities are efficient, unbiased, objective, and scientifically sound.

### **Bridging Science and Management**

The success of the GCDAMP in general and the effective use of scientific information in the adaptive management process in particular are confounded by the following factors:

1. The ability of the GCMRC to design studies that will produce relevant scientific information depends on how well the GCDAMP managers clearly define and agree on resource goals and desired outcomes. This has been a challenge for the GCDAMP because of value-based conflicts and the varying levels of collaborative skills of GCDAMP stakeholders.
2. To be successful, GCMRC scientists and GCDAMP managers must work together as partners—partners who recognize that they both have distinct but complementary roles. In some cases, the roles and responsibilities of the various groups and entities involved in the GCDAMP are not well defined, understood, or respected. In other cases, there is a perceived imbalance of power among stakeholders that limits their effectiveness influencing GCDAMP decisions and direction.
3. The success of the GCDAMP is dependent not only on the ability of the GCMRC to produce scientific information that is relevant to management needs, but also upon the effective use of that information by managers in the decisionmaking process. The challenge for the GCMRC is to synthesize large amounts of diverse and often highly technical data into a form that is relevant to a decision with implications for multiple resources in different areas and time frames. The challenge for managers is to rely on synthesized information in the decisionmaking process.

The GCMRC proposes a collaborative strategy among scientists and GCDAMP participants over the next 5 years to improve the effectiveness of the GCDAMP and the use of scientific information. A major element of this strategy will include using the SA review of the GCDAMP to develop an action plan for addressing priority issues, needs, or opportunities related to the effectiveness of the GCDAMP and the use of scientific information in the adaptive management process. Additionally, the feasibility of developing and using decision-support systems will be assessed following the SA evaluation planned for FY2007 to discover opportunities for improving interdisciplinary, integrated science in the GCDAMP. In FY2008–

09, the GCMRC will issue a contract to assess the feasibility of using decision-support systems and tools to facilitate the integration of scientific data and information in GCDAMP decisionmaking processes, including resource tradeoff analyses, risk assessments, and innovative organization and display of data. The feasibility assessment will result in a prioritized implementation plan, schedule, and budget. Recommendations will be implemented in FY2009–11 in accordance with established budget priorities.

#### FY2007. GCDAMP Effectiveness Workshop (Project PLAN 12.P2.07)

In FY2006–07, the SA will conduct a limited review of the effectiveness of the GCDAMP. Results of the review and other information provided by the GCDAMP will be used by the GCMRC as a basis for organizing a 2- to 3-day workshop to develop an action plan for addressing priority issues, needs, or opportunities related to the effectiveness of the GCDAMP and the use of scientific information in the GCDAMP process. The workshop, which will include GCDAMP participants and national experts in collaboration, partnerships, Native American involvement, and conflict resolution, will occur in early 2007. The workshop will be designed and conducted in cooperation with GCDAMP participants. The GCMRC recommends the establishment of an ad hoc group made up of representatives of the TWG, AMWG, SA, and the Secretary's Designee to serve as a steering committee for the workshop. The action plan developed through the workshop will be implemented and tested over the 2008–11 program period.

#### FY2007–08. Enhancing the CEM to Identify Critical Ecosystem Interactions and Data Gaps (Project PLAN 12.P1.07).

In FY2007–08, the GCMRC will work with the SA to identify and incorporate more robust integrated ecosystem science approaches into the GCMRC program. The first step will be to evaluate redesign and expansion of the CRE CEM.

In FY2008 and FY2009, the GCMRC proposes to recruit a part-time/visiting ecosystem scientist/ecologist to work with GCMRC staff and cooperators to develop and implement an integrated, interdisciplinary ecosystem science program. The primary focus of the visiting scientist will be to integrate SA recommendations and the results of the CEM exercise into the GCMRC science program.

### **Logistical Support**

Implementation of the GCMRC mission to provide scientific information to the GCDAMP begins with effective coordination of all technical and logistical support of research activities. The objective of this activity is to provide logistical support for field activities that emphasizes safety and cost effectiveness while complying with all permitting requirements with the NPS and all other Federal, State, and Tribal agencies. Research projects supported by the GCMRC must acquire required permits for project activities in compliance with Federal, State, Tribal, and local agencies. The program integrates both permitting and logistical operations.

Research activities conducted within GRCA and Glen Canyon National Recreation Area require NPS Research and Collecting Permits and Access Permits for all river launches, backcountry use, overflights, and media (filming) production. All permits acquired for GCMRC-

supported projects will be processed and submitted through the NPS Research Coordination and Support Program.

The GCMRC will provide complete logistical support for 30–50 research, monitoring, and administrative river trips through Grand Canyon annually. These trips range in length from 7 to 21 days and from 4 to 36 people in size. Trips will use a variety of motor- and oar-powered boats operated by contracted boat operators. Projects operating in the Glen Canyon reach of the Colorado River (GCD to Lees Ferry) will be supported by a variety of motor-powered boats operated by GCMRC researchers and contracted boat operators. Additionally, research activities on the LCR and at other locations outside of GRCA boundaries are supported by helicopter services contracted with Reclamation. Ground-based support for research activities outside of the river corridor are also accomplished with the use of vehicles leased by the GCMRC.

#### FY2007–11. Logistics Base Costs (Project SUP 12.S1.07)

The GCMRC will use government-owned boats and river logistical equipment in conjunction with a contracted vendor who supplies technical and logistical boat operators. Put-in and take-out transportation is provided through the use of Government Service Administration leased vehicles and contracted shuttle drivers.

Effective communication with principal investigators and sensitivity to and awareness of the challenges they face in implementing their studies enable the GCMRC to offer more customized (and therefore more cost-effective and productive) logistical support than in the past. Retaining control over support of trips also facilitates compliance with NPS and other regulations and allows greater control over issues that are sensitive for the general public and the recreational river community.

The logistics budget will be distributed to GCMRC projects based on a formula proportional to use of services. The formula takes into account contractor costs, trip size and length, and a percentage of operating expenses, including salaries, equipment replacement, and permitting costs.

### **Data Acquisition, Storage, and Analysis**

The objective of the DASA Program is to provide timely support for the acquisition, archiving, retrieval, analysis, and modeling of all scientific datasets and reports. These activities support most of the scientific projects undertaken by the GCMRC, making them a critical support function for advancing the 12 GCDAMP goals.

#### FY2007–11. Preparation for Monitoring Data Acquisition (remote sensing) (Project DASA 12.D1.07)

This project provides multispectral digital images used for detecting macro-scale changes in habitat conditions throughout the Colorado River corridor below GCD. These data are fundamental inputs to many of the GCMRC scientific studies and models used for spatial analysis and change detection. Quadrennial overflights are proposed as a broad strategy for the long-term monitoring program because gathering data through overflights at 4-year intervals balances budget constraints with the need to detect longer term (decade-scale) resource trends. The next planned overflight is scheduled to occur in FY2009; the last overflight was conducted in May 2005.

FY2007–11. Grand Canyon Integrated Oracle Database Management System (Project DASA 12.D2.07)

This project establishes an electronic repository for project data and the tools necessary to analyze and interpret these data, providing a fundamental support service to GCMRC scientific investigations and decision-support processes. Working with data stewards from each scientific program at GCMRC, the integrated database will accommodate both newly collected and existing data. Developing an integrated database design also involves extensive review of existing datasets and current data-collection protocols. Tools, including Web-based interfaces, will be developed that enable users to extract related datasets and perform appropriate analyses.

FY2007–11. Library Operations (Project DASA 12.D3.07)

The GCMRC library acts as the physical repository for reports and data generated by GCMRC scientists and cooperators. The library also acquires and makes available resources related to the Colorado River, Grand Canyon, and adaptive management. To facilitate the use of library materials, a searchable catalogue of library holdings is available through the GCMRC Web site. The Web-based catalogue also provides links to downloadable versions of project reports and other materials. Library staff are available to assist with research needs and the acquisition of materials needed to support monitoring and research activities. The library is available to the general public.

FY2007–11. Legacy Analog Data Conversion (analog-to-digital reports and imagery) (Project DASA 12.D4.07)

Through this project GCMRC staff will convert all materials in the library to digital format and make them available from the GCMRC Web site. A major emphasis of this effort is the conversion of analog overflight images to digital images to extend the historical information available for targeted resources, including sandbars, backwaters, and vegetation. The objective of the project is to make the specialized materials maintained by the GCMRC library easily available to users outside of Flagstaff, Ariz., and to protect unique items from damage or loss.

FY2007–11. GIS General Support for Integrated Analyses and Projects, GIS Lead (Project DASA 12.D5.07)

The objective of this project is to support science program activities through spatial database development, programming, and analysis. Most GCMRC projects have a spatial component, and GIS provides a means by which data collected in the CRE can be catalogued within a consistent spatial reference system. At the most basic level, this allows for the overlaying and querying of datasets collected from any and all projects within the GCMRC. The project will also provide a higher level of support for specific GIS application development and analysis. Services provided by the project include the creation of maps suitable for publications; design and printing of maps and graphics for posters; creation of improved base maps for Lake Powell and Grand Canyon; instructional sessions for staff, cooperators, and contractors on GIS layer development, integration, and analysis; and advanced spatial analysis for monitoring projects.

#### FY2007–11. Integrated Analysis and Modeling—Mapping Shoreline Habitat Changes (Project DASA 12.D6.07)

The main objective of the project is to study the shoreline environment along the Colorado River downstream of GCD. The project will analyze multiyear multispectral digital imagery. A baseline dataset of shoreline habitat currently exists as a linear classification of six habitat types at 8,000 cfs for the year 2000. Three other remote-sensing datasets from 2002–5 will be used to extend the time series of the shoreline habitat for a 5-year period. Additionally, this classification needs to be expanded into higher stages (above 8,000 cfs up to at least 45,000 cfs) to better correlate shoreline habitat with fish data and recreation habitat data collected by GCMRC and its cooperators. The original classification scheme for the shoreline will be extended to include backwater habitats, providing an update to the existing backwater dataset (developed by USU) up to 2005 (Goeking and others, 2003). In addition to the classification effort, an automated suite of methods could be developed to facilitate shoreline change detection across a range of stages.

#### FY2007–11. Survey Operations (Project SUP 12.S2.07)

All spatial data collected under the direction of the GCMRC requires referencing to the primary geodetic control network established by the National Geodetic Survey (NGS) and the GCMRC. The geodetic control network is the framework for the GIS. The primary network has been expanded to secondary and tertiary levels of control within CRE river reaches. Consistent methods and protocols have been developed for spatial data collection and its integration into the GIS. Trained GCMRC survey staff support monitoring and research by collecting survey data with these protocols and delivering the data in formats consistent with data standards.

#### FY2007–11. Control Network (Project SUP 12.S3.07)

The objective of this project is to develop a high-precision control network throughout the CRE and at locations required for accurate positions and elevations of past, current, and future datasets. The goal of the project is the expansion of the control network into the necessary areas before collecting the spatial data required by GCMRC research and core-monitoring activities. Having stable control monuments and accurate coordinates completed before spatial data acquisition begins reduces the effort required in postprocessing and promotes conservation of both human and funding resources. Historical datasets are accurately rectified for integration into the database.

### **Administrative and Information Technology Support**

The objective of this activity is to provide a smooth-running, transparent administrative operation that enables GCMRC scientists to focus on their research rather than on the administrative details. The Southwest Biological Science Center (SBSC) provides the oversight and management of facilities, burden, and overhead; personnel issues; expenditure tracking; processing and financial management of cooperative and interagency agreements; processing of contracts; timekeeping; bank card tracking and reconciliation; travel planning and voucher processing; and liaison activities among the USGS administrative groups (Western Region Budget and Fiscal Services and Contracting Offices, Headquarters in Reston, and the Biological Headquarters). This activity is closely involved with the USGS nationwide budget-tracking and

reporting system known as BASIS+, which is used by the USGS Headquarters and Regional offices to make their annual reports to Congress and to respond to congressional inquiries with turnaround times as short as 12 h. In addition, the SBSC Information Technology Department supports technology needs for various GCMRC program areas.

#### **FY2007–11. Administrative Operations (Project ADM 12.A1.07)**

The goals of this project are to provide budgetary oversight and support to the Chief, Program Managers, and all employees of GCMRC so that they may conduct their responsibilities in the most ethical, professional, and efficient manner possible; to enable the employees to be unburdened, to the largest extent possible, by mundane administrative matters; and to support the USGS and the GCMRC missions of conducting unbiased scientific research.

#### **GCMRC Component of SBSC Systems Administration Support (Project ADM 12.A5.07)**

The SBSC through its Information Technology Department supports a variety of technology needs for the GCMRC, including computer security, systems administration, procurement of new servers and computers, and Web site development and maintenance. The goal of the IT Department is to ensure that the GCMRC is able to conduct scientific and administrative functions smoothly and with the least possible disruption in service. These support, development, and maintenance services are cost shared between the GCMRC and the SBSC. The IT Department also maintains the security of GCMRC and SBSC networks up to current Federal standards and ensures that all those who access the systems meet Federal security standards to protect personal information and scientific research that has not yet been released to the public. The IT Department also works in coordination with DASA to provide full and easy access to publicly released data via the GCMRC Web sites.

#### **FY2007–11. AMWG/TWG Participation (Project ADM 12.A3.07)**

The goal of this project is to create an account to hold and track funds for the travel expenses of employees who participate in AMWG and TWG meetings.

## **CHAPTER 3. Funding for Proposed FY2007–11 Monitoring and Research Plan**

Table 3 identifies the total anticipated funding to support GCMRC monitoring and research activities related to the GCDAMP, including anticipated power revenues, continued Reclamation funding for Lake Powell monitoring, and anticipated USGS appropriations to support the GCDAMP activities. In general, funding priorities will be established in cooperation with the GCDAMP based on the guidance included in the final GCMRC SSP and MRP. Funding emphasis will be given to address the SSQs associated with priority AMWG questions and information needs (appendix A). Specific funding priorities will be established through the biannual work plan planning process.

To respond to expanding science needs, the GCMRC will work with the AMWG and the Secretary's Designee to (1) develop greater support from the Secretary of the Interior and Congress to maintain existing budgets and to expand budgets to meet critical needs that cannot be addressed within current budget constraints, and (2) explore cooperative partnerships with GCDAMP agencies and others to address critical monitoring and research needs. For example, GCMRC will work with the DOI and Reclamation to secure the additional funds to assist with evaluating and testing of a TCD for GCD. In addition, GCMRC will work with USGS and the DOI leadership to secure additional base funding to address high-priority monitoring and research needs related to the GCDAMP.

**Table 3.** Total anticipated funding to support the GCMRC Monitoring and Research Plan in fiscal years 2007 through 2011 (tribal participation is not included in this table).

| <b>FUNDING SOURCES</b>  | <b>Fiscal year (FY) 2007</b> | <b>FY2008</b>       | <b>FY2009</b>       | <b>FY2010</b>       | <b>FY2011</b>       | <b>TOTALS</b>       |
|---|------------------------------|---------------------|---------------------|---------------------|---------------------|---------------------|
| Power revenues under cap—estimated USGS portion <sup>(1)</sup>  | \$8,094,034                  | \$8,336,855         | \$8,586,961         | \$8,844,569         | \$9,109,907         | \$42,972,326        |
| USGS appropriations—assistance with burden costs (cost share)   | \$1,000,000                  | \$1,000,000         | \$1,000,000         | \$1,000,000         | \$1,000,000         | \$5,000,000         |
| USGS Appropriations—assistance for scientific research outside of but related to GCDAMP goals and activities <sup>(2)</sup> | 0                            | \$1,000,000         | \$1,000,000         | \$1,000,000         | \$1,000,000         | \$4,000,000         |
| Reclamation operations and maintenance (Water Quality Lake Powell and Tailwaters Agreement) <sup>(1)</sup>                  | \$226,659                    | \$233,459           | \$240,463           | \$247,676           | \$255,107           | \$1,203,364         |
| <b>TOTAL AVAILABLE FUNDS</b>  | <b>\$9,320,693</b>           | <b>\$10,570,314</b> | <b>\$10,827,424</b> | <b>\$11,092,245</b> | <b>\$11,365,014</b> | <b>\$53,175,690</b> |

<sup>(1)</sup> Fiscal year cost increases estimated at an average CPI increase of 3% per historical application used by the Bureau of Reclamation.

<sup>(2)</sup> This additional appropriated funding has been requested but has not yet been approved.

## **APPENDIX A. AMWG Priorities and Associated Strategic Science Questions from the GCMRC Strategic Science Plan**

**AMWG Priority 1:** Why are the humpback chub not thriving, and what can we do about it? How many humpback chub are there and how are they doing? (GCDAMP Goal 2)

### Key Strategic Science Questions

1. To what extent are adult populations of native fish controlled by production of young fish from tributaries, spawning and incubation in the main stem, survival of young-of-year (YoY) and juvenile stages in the main stem, or by changes in growth and maturation in the adult population as influenced by main stem conditions? [FY06 –FY11]
2. Does a decrease in the abundance of rainbow trout and other cold and warm water nonnatives in Marble and eastern Grand Canyons result in an improvement in the recruitment rate of juvenile humpback chub to the adult population? [FY06–FY11]
3. Do rainbow trout immigrate from Glen to Marble and eastern Grand Canyons, and, if so, during what life stages? To what extent do Glen Canyon immigrants support the population in Marble and eastern Grand Canyons? [FY07–FY11]
4. Can long-term decreases in abundance rainbow trout in Marble and eastern Grand Canyons be sustained with a reduced level of effort of mechanical removal or will re-colonization from tributaries and from downstream and upstream of the removal reach require that mechanical removal be an ongoing management action? This question also applies to future removal programs targeting other nonnative species. [FY07–FY11]
5. What are the important pathways, and the rate of flux among them, that link lower trophic levels with fish and how will they link to dam operations? [FY06–FY09]
6. Are trends in the abundance of fish populations, or indicators from fish such as growth, condition, and body composition (e.g., lipids), correlated with patterns in invertebrate flux? [FY06–FY09].
7. Which tributary and mainstem habitats are most important to native fishes and how can these habitats best be made useable and maintained? [FY 08–FY09].
8. How can native and nonnative fishes best be monitored while minimizing impacts from capture and handling or sampling? [FY07–FY11].

**AMWG Priority 2:** Which cultural resources, including Traditional Cultural Properties (TCP), are within the Area of Potential Effect, which should we treat, and how do we best protect them? What is the status and trends of cultural resources and what are the agents of deterioration? (GCDAMP Goal 11).

### Key Strategic Science Questions

1. Do dam controlled flows affect (increase or decrease) rates of erosion and vegetation growth at archaeological sites and TCP sites, and if so, how? [FY07–FY11]
2. How do flows impact Old High Water Zone terraces in the CRE (where the majority of archaeological sites occur), and what kinds of important information about the historical ecology and human history of the CRE are being lost due to ongoing erosion of the Holocene sedimentary deposits? [FY04–FY11]
3. If dam controlled flows are contributing to (influencing rates of) archaeological site/TCP erosion, what are the optimal flows for minimizing future impacts to historic properties? [FY09–FY11]
4. How effective are various treatments (e.g., check dams, vegetation management, etc.) in slowing rates of erosion at archaeological sites over the long term? [FY06–FY11]
5. What are the TCPs in the CRE, and where are they located? [FY06–FY11]
6. How can tribal values/data/analyses be appropriately incorporated into a science driven adaptive management process in order to evaluate the effects of flow operations and management actions on TCPs? [FY06–FY08]
7. Are dam controlled flows affecting TCPs and other tribally-valued resources in the CRE, and, if so, in what respects are they being affected, and are those effects considered positive or negative by the tribes who value these resources? [FY06–FY11]

**AMWG Priority 3:** What is the best flow regime? (GCDAMP Goals 1-11)

### Key Strategic Science Questions

1. Is there a “Flow-Only” operation (i.e. a strategy for dam releases, including managing tributary inputs with BHBFs, without sediment augmentation) that will restore and maintain sandbar habitats over decadal time scales? [FY08–FY11]
2. To what extent could predation impacts by nonnative fish be mitigated by higher turbidities or dam controlled high-flow releases? [FY07–FY08]
3. What are the hydropower replacements costs of the Modified Low Fluctuating Flow (MLFF) (annually, since 1996)? [FY07–FY08]
4. What are the projected hydropower costs associated with the various alternative flow regimes being discussed for future experimental science (as defined in the next phase experimental design)? [FY06–FY07]

5. How is invertebrate flux affected by water quality (e.g., temperature, nutrient concentrations, turbidity) and dam operations? [FY06–FY09]
6. What Glen Canyon Dam operations (ramping rates, daily flow range, etc.) maximize trout fishing opportunities and catchability? [FY07–FY08]
7. How do dam controlled flows affect visitors’ recreational experiences, and what is/are the optimal flows for maintaining a high quality recreational experience in the CRE? [FY07–FY08]
8. What are the drivers for recreational experiences in the CRE, and how important are flows relative to other drivers in shaping recreational experience outcomes? [FY07–FY09]
9. How do varying flows positively or negatively affect campsite attributes that are important to visitor experience? [FY09–FY11]
10. How can safety and navigability be reliably measured relative to flows? [FY07–FY08]
11. How do varying flows positively or negatively affect visitor safety, health, and navigability of the rapids? [FY07–FY09]
12. How do varying flows regimes positively or negatively affect group encounter rates, campsite competition, and other social parameters that are known to be important variables of visitor experience? [FY07–FY09]

**AMWG Priority 4:** What is the impact of sediment loss and what should we do about it? (GCDAMP Goal 8)

Key Strategic Science Questions

1. Is there a “Flow-Only” operation (i.e. a strategy for dam releases, including managing tributary inputs with BHBFs, without sediment augmentation) that will restore and maintain sandbar habitats over decadal time scales? (FY 08–FY11)
2. How important are backwaters and vegetated shoreline habitats to the overall growth and survival of YoY and juvenile native fish? Does the long-term benefit of increasing these habitats outweigh short-term potential costs (displacement and possibly mortality of young humpback chub) associated with high flows? [FY07–FY11]

**AMWG Priority 5:** What will happen when we test or implement the Temperature Control Device (TCD)? How should it be operated? Are safeguards needed for management? (GCDAMP Goals 1–4 and 7–10)

Strategic Science Questions

1. How do dam release temperatures, flows (average and fluctuating component), meteorology, canyon orientation and geometry, and reach morphology interact to determine mainstem and near shore water temperatures throughout the CRE? [FY06–FY08]
2. How is invertebrate flux affected by water quality (e.g., temperature, nutrient concentrations, turbidity) and dam operations? [FY06–FY08]
3. To what extent do temperature and fluctuations in flow limit spawning and incubation success for native fish? [FY03–FY08]
4. What is the relative importance of increased water temperature, shoreline stability, and food availability on the survival and growth of YoY and juvenile native fish? [FY03–FY08]
5. Will increased water temperatures increase the incidence of Asian Tapeworm in humpback chub or the magnitude of infestation, and if so, what is the impact on survival and growth rates? [FY03–FY08]
6. Do the potential benefits of improved rearing habitat (warmer, more stable, more backwater and vegetated shorelines, more food) outweigh negative impacts due to increases in nonnative fish abundance? [FY07–FY11]
7. How do warmer releases affect viability and productivity of native/nonnative vegetation? [FY07–FY11]

Timing and relative abundance can be addressed quantitatively by relating the catches in the current GCMRC database to LCR flow data; GCMRC has been pursuing this question in FY2007 and will continue in later years. Determining absolute abundances would require good survivorship of captured and tagged young fish and high likelihood of capturing tagged young fish, both of which are tenuous assumptions. |

|     |  |               |                                      |   |   | size/trend.  |
| 40  | 3.5, A   | 1             | 2.3.3                                | How does nonnative fish control/affect disease/parasite loads? (Note: The concept is if there are fewer hosts, there will be a lower incidence of parasites.) | <b>SA 1.</b> What are the most limiting factors to successful HBC adult recruitment in the mainstem: spawning success, predation on YoY and juveniles, habitat (water temperature) pathogens, adult maturation, food availability, competition?   |  |
| 41  | 3.5, A   | 6+            | 4.2.7                                | What dam release patterns most effectively maintain the Lees Ferry RBT trophy fishery while limiting RBT survival below the Paria River?                      | <b>SSQ 3-6.</b> What GCD operations (ramping rates, daily flow range, etc.) maximize trout fishing opportunities and catchability?  | This question would be most appropriately addressed as an LTEP study.  |
| 42  | 3.5, A   | 2             | 11.1.2                               | What are the historic properties within the area of potential effects?  | <p><b>SSQ 2-1.</b> Do dam controlled flows increase or decrease rates of erosion and vegetation growth at arch sites and TCPs, and if so, how?</p> <p><b>SSQ 2-2.</b> How do flows impact OHWZ terraces in the CRE, and what kinds of important information about the historical ecology and human history of the CRE are being lost due to ongoing erosion of the Holocene terraces?</p> <p><b>SSQ 2-7.</b> Are dam controlled flows affecting TCPs and other tribally-valued resources in the CRE, and if so, in what respects are they being affected, and are those effects considered positive or negative by the tribes who value those resources?</p> <p><b>CMIN 11.1.1</b> (SPG revised) Determine the condition and integrity of prehistoric and historic sites in the CRE through tracking rates of erosion, visitor impacts, and other relevant variables. Determine the condition</p> | The RIN question was answered in the 1995 EIS: 336 archaeological sites. There are still uncertainties regarding which sites are affected by which specific aspects of dam operations, and how dam processes interact with other elements of the environment to effect those changes; these uncertainties are being addressed through R&D studies in FY2007–09. There are also continuing uncertainties about the numbers and locations of TCPs (see comment below). Reclamation, as lead agency for Section 106 compliance, has the responsibility for completing TCP identification. |

How do flow rates and water quality parameters at seeps and springs compare with historic measurements? | <b>SSQ 2-1.</b> Do dam controlled flows affect (increase or decrease) rates of erosion and vegetation growth at archaeological sites and TCP sites, and if so, how?                                 | Current vegetation projects address species composition and distribution, but no projects are looking at effects of flow rates or water quality. The effects of experimental flows on vegetation will be a component of the LTEP, but specifics of the experiment have not yet been determined. Current monitoring is consistent with CMINs for this resource. |
| 182 | 9, A   |               | 6.6.4                                | What is the distribution, patch size, total area, and composition of seep and spring communities and the flow rate and water quality of all seeps and springs within the CRE?   | None proposed.  | Current vegetation projects address species composition and distribution, but no projects are looking at effects of flow rates or water quality. Effects of experimental flows on vegetation will be a component of the LTEP, but specifics of the experiment have not yet been determined. Current monitoring is consistent with CMINs for this resource.     |
| 183 | 9, A   |               | 6.7.4                                | How has the abundance, distribution and reproductive success of SWWF changed since dam closure (1963), high flows (1984), interim flows (1991) and the implementation   | None proposed.  | SWWF issues are currently being managed by NPS with USFWS.   |

| <b>No.</b> | <b>Adaptive Management Work Group (AMWG) Sequence Number and Category</b> | <b>AMWG Priority</b> | <b>Research information needs (RIN) no.</b> | <b>RIN text</b>  | <b>Strategic science questions (SSQs), relevant core-monitoring information needs (CMINs), and Science Advisor (SA) questions. Questions listed below are from the Monitoring and Research Plan (MRP).</b> | <b>Comments</b>  |
|------------|---|----------------------|---|--|--|--|
|            |   |                      |   | of ROD operations (1996)?  |  |  |
| 184        | 9, A  |                      | 7.3.3                                       | How do dam operations affect reservoir limnology?  | (No additional SSQ because of relatively low AMWG priority.)   | This is a legitimate science question that potentially warrants further study in the LTEP.   |
| 185        | 9, A  |                      | ** SIN<br>8.5.1                             | How do sandbar textures influence biological processes?  | (No additional SSQ because of relatively low AMWG priority.)   | This SIN is a legitimate science question and should be pursued as support becomes available.  |
| 186        | 9.5, C  |                      | 3.1.1                                       | What information (including technical, legal, economic, and policy issues) should be considered in determining the feasibility and advisability of restoring pikeminnow, bonytail, roundtail chub, river otter, or other extirpated species? | None proposed.   | Policy and management question. If restoration of one or more of these species is a priority, then GCMRC can provide scientific support.                                     |
| 187        | 9.5, A  |                      | 8.5.3                                       | What is the pre- and postdam range of grain-size in fine-sediment deposits, by reach?  | None proposed.   | See several publications containing information on this topic: Howard and Dolan, 1981; Schmidt and Graf, 1990; Topping and others 2005; Topping and others, 2000a and 2000b. |
| 188        | 10, A   |                      | 4.1.1                                       | What is the target proportional stock density (i.e., tradeoff between numbers and size) for RBT in the Lees Ferry reach?   | None proposed.   | To a large degree, the target is a management decision, but current monitoring efforts provide supporting information.   |
| 189        | 10, A   |                      | 4.1.4                                       | How does the genetics or “strain” of RBT in the Lees Ferry reach influence the average size of fish creeled by anglers?  | (No additional SSQ because of relatively low AMWG priority.)   | This information need is not currently being addressed.  |

| No. | Adaptive Management Work Group (AMWG) Sequence Number and Category | AMWG Priority | Research information needs (RIN) no. | RIN text   | Strategic science questions (SSQs), relevant core-monitoring information needs (CMINs), and Science Advisor (SA) questions. Questions listed below are from the Monitoring and Research Plan (MRP).  | Comments   |
|-----|--|---------------|--------------------------------------|--|--|--|
| 190 | 11, A  |               | 2.5.1                                | If RBS were stocked into the CRE, what is the risk that hybridization with FMS would compromise the genetic integrity of either species?     | (No additional SSQ because of relatively low AMWG priority.)   | RBS are not a high GCDAMP priority at this time.   |
| 191 | 11, A  |               | 2.5.2                                | How do existing RBS and FMS affect the genetic integrity of either species? What are the factors contributing to this ongoing hybridization? | None proposed.   | RBS are not a high GCDAMP priority at this time. (This question is well addressed in a paper by D.G. Buth and others, 1987, which suggests that the native level of hybridization was not detrimental to either species.)  |
| 192 | 11, C  |               | 2.5.6                                | What are the measurable criteria that would need to be met to remove jeopardy for RBS in the CRE?  | None proposed.   | Policy question.   |
| 193 | 11, A  |               | 7.3.2                                | How accurately can modeling predict reservoir dynamics and operational scenarios?  | None proposed.   | Not a high GCDAMP priority. Outside funding for modeling Lake Powell is identified in the MRP. The Bureau of Reclamation has developed a model for Lake Powell reservoir, but it has not been published in the peer reviewed literature to date. Therefore, the answer to this question remains unknown. |
| 194 | 11, A  |               | 9.1.1                                | What are the attributes of a quality river experience? (How do you define a quality river experience?)                                       | <b>SSQ 3-7.</b> How do dam controlled flows affect visitors' recreational experiences, and what are the optimal flows for maintaining a high quality recreational experience in the CRE?<br><b>SSQ 3-8.</b> What are the drivers for recreational experiences in the CRE, and how important are flows relative to other drivers in shaping recreational experience outcomes? | This is largely an NPS management decision. Social science studies can provide data on what the public considers to be a quality river experience, but ultimately NPS must determine what type of experience they are managing for.  |

| No. | Adaptive Management Work Group (AMWG) Sequence Number and Category | AMWG Priority | Research information needs (RIN) no. | RIN text   | Strategic science questions (SSQs), relevant core-monitoring information needs (CMINs), and Science Advisor (SA) questions. Questions listed below are from the Monitoring and Research Plan (MRP).                       | Comments   |
|-----|--|---------------|--------------------------------------|--|---|--|
|     |  |               |                                      |  | (See also SSQ 3-9, 3-10, 3-11, and 3-12.)   |  |
| 195 | 11, A  |               | 9.1.2                                | Determine the appropriate carrying capacity for recreational activities within the CRE.  | None proposed.  | Appropriate carrying capacity is dependent on the type of recreational experience that the river corridor is being managed for and amount of crowding NPS is willing to allow; therefore, this RIN must be addressed by NPS managers in consultation with the public. Once target levels for crowding and encounter rates have been established, we can provide data on how flows are changing social encounters and campable area in relation to those targets. |
| 196 | 11, A  |               | 9.1.3                                | How do ongoing inputs of coarse-sediment from tributaries diminish or enhance navigability of rapids throughout the CRE?   | <b>SSQ 3-10.</b> How can safety and navigability be reliably measured relative to flows?<br><b>SSQ 3-11.</b> How do varying flows positively or negatively affect visitor safety, health, and navigability of the rapids? | This was to be addressed as a component of the safety study proposed for FY2007, and now deferred to FY2008 or FY2009.   |
| 197 | 11, A  |               | 12.1.2                               | What are the use (e.g., hydropower, trout fishing, rafting) and nonuse (e.g., option, vicarious, quasi-option, bequest and existence) values of the CRE?                                     | None proposed.  | A question for the socioeconomic PEP to consider.  |
| 198 | 11, A  |               | 12.1.3                               | How does use (e.g., hydropower, trout fishing, rafting) and nonuse (e.g., option, vicarious, quasi-option, bequest and existence) values change in response to an experiment performed under | <b>SSQ 3-4.</b> What are the projected costs associated with the various alternative flow regimes being discussed for future experimental science (as defined in the next phase experimental design)?                     |  |

| No. | Adaptive Management Work Group (AMWG) Sequence Number and Category | AMWG Priority | Research information needs (RIN) no. | RIN text   | Strategic science questions (SSQs), relevant core-monitoring information needs (CMINs), and Science Advisor (SA) questions.
